And similarly herein appears to lie the possible explanation of the association of the pernicious attacks with the malignant tertian infections. Perniciousness being the result of the stasis produced and the subsequent clogging and infraction of the capillaries. The generally severer and more lasting effects of malignant tertian infection, their more insidious course, the frequently anomalous symptoms, the continuance of fever for days in spite of specific treatment and when parasites cannot be found, should make us give due consideration to the fact that in this disease we may have a condition of erythro-katalysis produced, similar to that which studied experimentally can be seen to lead to quite marked organic disease. (We may remark here, in parenthesis, that experiments on dogs have suggested to us the possibility of erythro-katalysis in a marked degree being concerned in the causation of post-hæmoglobinuric and certain other anomalous fevers, such as the "symptomatic fever" of Kelsch and Keiner, in which a febrile condition exists uninfluenced by quinine and apparently unrelated to any specific cause, but associated almost invariably with evidence of continued blood destruction.)

CAUSATION OF BLACK-WATER FEVER.
What relation do these observations bear to the

causation of Black-water Fever?

We have previously referred to the fact that by immunising an animal of species A against injections of the red corpuscles of species B, we produced in A a serum capable of dissolving the blood cells of B in vitro, and when injected in vivo of producing symptoms under certain conditions closely resembling those of Black-water Fever. It may be asked whether it is possible to produce a similar effect by injecting an

animal with blood from another individual of the same species. This is possible, for Ehrlich and others have produced in this way a number of different iso-lysins. Still further pushing the question we may ask if it is not possible to immunise an animal against its own blood cells? This has been attempted, but it is not easy, apparently because of certain regulating powers possessed by the organism, which largely serve to protect it from such a condition. Nevertheless, Ehrlich records that he did once produce an autolysin in this way. Under pathological conditions, however, we often meet with effects that we cannot produce experimentally, and the occurrence of autolysins as a result of disease is very probable.

of disease is very probable.

What actually happens during the process of immunising an animal of species A to the red cells of an animal of another species B? Metchnikoff has investigated this question and states as the result of numerous experiments that whenever foreign blood cells are injected into an animal, the primary phenomenon to be observed is an extensive phagocytosis or resorption of the foreign blood elements. In attempting, therefore, to produce an autolysin experimentally we endeavour by some means to force an organism to deal repeatedly with its own red cells in the same manner that it would act towards foreign blood corpuscles; in other words, we attempt to stimulate the resorption of a large number of an animal's own blood

cells.

In Black-water Fever, as we have already indicated, we have reason to believe that we are not dealing with the effects of a toxin elaborated by the malarial parasite, but with the action of substances produced by the human organism itself; in other words, with the effects of an autolysin. And if human autolysin is to occur, can we think of any diseased condition more likely to produce it than malaria? Malaria actually gives rise within man's body to the very condition we try to bring about in the attempt to produce an autolysin experimentally. Under the circumstances which appear necessary for the occurrence of Black-water Fever, the peculiar character of which we have briefly indicated, it is obvious that repeated and persistent blood destruction and resorption must result, and we see again that if our hypothesis, which is only hypothesis, be the true one, why the malignant tertian parasite, its special action upon the red cells and consequent stimulation to their phagocytosis, should above all be the one concerned in the causation of Black-water Fever

All this is, of course, hypothesis, but it may serve its purpose of indicating in a very broad and general way how Black-water may be malarial in origin and yet not be malaria.

# ACUTE MULTIPLE SCLEROSIS.

By Professor HERBERT KOCH, M.D.,

Director of the Neurological Institute, Vienna.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

of a disease often difficult to diagnose and more unsatisfactory to treat. It is eminently a chronic disease, but cases are on record where an acute form has attended a group of these multiple centres. Marburg seems to have been the first to recognise this fact of rapid inflammatory centres in his disquisition on the so-called "Multiple Sclerosis." In this exposition of the subject he includes a series of acute cases culled from literature of its history. Bischofskys, Schobs and Volsch have also given examples in multiple sclerosis of an acute character, while others have included myelitis in their clinical history. From the proximity of the morbid changes it is easy to understand how multiple sclerosis and myelitis can be represented in the same clinical group. The follow-

ing minute and detailed history may serve as a classical example of the clinical history and

pathological anatomy of the disease: -Alois, æt. 30, fireman, had always been well from childhood, even without history of any of the children's diseases. Had a good family history, and no trace of any nerve disease to be discovered. Last year he was attacked with erysipelas in the face, from which he soon recovered. Three weeks ago, after a heavy day's work, he felt tired and exhausted, particularly in the left leg, which was numb and void of feeling, this extending from the hip to the toes. This paræsthesia extended to the left side of the penis, but the right remained perfectly normal, stopping exactly at the middle Next day as patient endeavoured to go to work he found that both legs were feeble and locomotion difficult. Eight days later patient was unable to move, the feet being quite helpless. From this time difficulty in urinating commenced, as well as in defæcation, the patient not knowing either were performed, except by ocular demon-The paræsthesia steadily increased when looking at a book or newspaper. Observed that the grasp of both hands was weak, that the thumb and index finger of the right hand were paræsthetic, but the paræsthesia of foot almost gone, while the right leg had become powerless. 28th.—Paræsthesia in the middle finger of the right hand appeared for the first time; 30th.-Paræsthesia invaded the whole of the right hand, while motor power in both hands was very low, right extremities feeling colder than left, and it was noticed for the first time that patient spoke badly, the tongue being more difficult to move as the patient expressed it.

On July 1st there was converging nystagmus, the right angle of the mouth was lower than the left, and guttural sounds were difficult to produce. On the 2nd the symptoms were more aggravated, the tongue more difficult, and the power of the ileft ileg reduced, the flickering before the eyes increased, and the upward movement of the ball limited. On this date all the cerebral nerves were tested. The first was normal; the second: objects swimming with letters in reading; third and fourth: left lids contracted bulbi convergent, but the converging nystagmus gone, except when looking to the extreme left or right; fifth, sixth and seventh nerves of face almost normal, except left slightly below, while tactile and pinching were normal; the changes in the eighth were nil, but those on the ninth, tenth, eleventh and twelfth were protrusion of the tongue, fibrillary contractions in the left side, no disturbance in taste, uvula drawn towards right, left side of buccal vault loose, while left gums are reduced in innervation.

On July 4th, right facial paresis. On the 5th, there was left facial paresis and the right had disappeared. Subjectively there was a feeling of deafness and loss of sensation in the left side of the face; fundus normal, paresis in right arm, but no shaking or ataxia.

but no shaking or ataxia.

On the 6th, the difficulty of speech returned, the tongue being drawn towards the right, movement towards left being difficult, with dyspnæa.

On 7th, nystagmus bad left side of face, and

right arm and leg paralysed.

8th.—Power of speech still worse, Singultus, pulse 12), tachycardia, left arm free and grasp of hand strong, but left leg paralysed, right arm powerless, right leg paralysed, but pelvis resisting, and patellar reflex in both legs active as well as the Achilles reflex. The Babinski test was

positive on both sides, but no clonus. The cremaster muscles had no reflex. The sensibility of the right thigh was lost for tactile and pricking, while in both upper extremities this was undisturbed.

10th.—Both eyes follow the finger from right to left, but not without nystagmus contraction suddenly after returning to the middle line. The fundus was still normal, but the skin had assumed an icteric colour.

On the 11th he died. The clinical diagnosis was expressed as:—"Encephalitis multiplex, præcipue pontis, myelitis disseminata."

The post-mortem was conducted by Prof. Paltauf the following day: Medium size, well built and muscular, although emaciated, and pale in appearance. The cranium was 17 centimetres = 6.8 inch in length and 15 = 6 inch broad. and strong. Inner surface smooth, red, covered with loose clots and fluid blood. Meninges on convex and basal surfaces have veins congested with brain substance soft and moderately filled with blood. The cortex reddish, ventricles not enlarged, but the subependymal vein distended at a point where it falls into the vena terminalis. The basal ganglia red, but no pathological change to be discovered. A horizontal section in front of the quadrigemina passed through a red centre in the right peduncle, 4 millimetres wide, and depressed. The substance was friable and soft, which was also true of the medulla oblongata, particularly the grey substance. The floor of the fourth ventricle was greatly depressed. The left olive body in the region of the pyramidal had a narrow quadrilateral appearance with a very small centre of grey matter, with a similar yellow colour in the right restiform body. At the pyramidal crossing on the right side anteriorly was found another circumscribed reddish-grey centre with a yellow nucleus which extended to the anterior horn of the cord. In the upper part of the cervical region the central part of the posterior column was similarly affected, this red centre extending to the third and fourth cervical nerves; anteriorly on the right side this red centre had an oval, reddish-grey sunken appearance. Externally on the left side in the lateral column the same red centres could be found, but the surroundings more swollen. In the lower part of the cervical region in the right anterior column was found a soft greyish centre, ill-defined, but extending down into the dorsal region with great swelling and extending a reddish condition to the posterior column.

Macroscopic investigation gave no further information, but there were present extensive bronchitis, broncho-pneumonia, particularly in the right apex; in lower lobes thrombosis with pleurisy in right side.

The histological results were still more interesting. The peripheral nerves were taken first and coloured with Weigert's solution, but nothing worth recording was found. The longitudinal sections were not normal. With Marchi's solution streaks of osmium and dark grey colourations were present. At these parts the nerves were thin, though the centre of Schwann was increased and associated with Eltzholz bodies.

The spinal cord was different. Some of the segments were quite free, while others were badly damaged, the lumbar region alone escaping, but the cervical and dorsal were the seat of the principal morbid changes, although no localised

centre could be chosen as primary, both anterior and posterior being involved in the general destruction. These centres varied from the size of a pin's head to the area of the entire section. These centres were of all shapes, round, oval and wedge, the latter occurring mostly on the surface of the cord. No secondary degeneration was present in the lumbar region. The pia mater was perivas-cular and thickened, but the ganglionic cells were unchanged.

The principal lesion in the spinal cord was about the upper part of the dorsal region. Portions removed with the gouge and coloured with Weigert's solution showed loose fibres in a transitory condition, while in the centre of these local changes a small portion of debris which, when treated with Hæmalaum, had the appearance of small, round cells, having the character of perivascular round cells with several nuclei. The cells were found along the arteria spinalis ventralis and even into the sulcus longitudinalis ventralis. neighbourhood of these centres the axis cylinder was swollen with œdema, but no hæmorrhage was present. At these parts in the cord the glia or ependyma was increased in cellular consistency, but not in fibrous. In the middle of the dorsal region where these centres were absent, the pia mater was considerably thickened, and perivascular, which was equally true of the lumbar region. We thus distinguished two different kinds of centre in the upper part of the dorsal region, viz., those of a simple round cell character, and those of a granular character, the latter, when coloured, with Weigert, had fine shadows as if containing fine granules of myelin. In the midst of one of these centres a few fibres were always to be found which, when cut, showed the axis cylinder lying loose in the sheath.

It should be noted that sclerosis in the true meaning of the term was not present; on the contrary, there was a profusion of perivascular round-cell infiltration, these round cells having a double character, one with a distinct nucleus and little protoplasm like lymphocytes, the other having an oval nucleus with a normal amount of plasma, but granular. In the older centres of the cervical region the same appearance prevailed, and Marchi's preparations negatived all secondary degeneration, although in several a few fat cells

were present.

In the medulla oblongata a large triangular centre with the base towards the periphery, involving the pyramids and olive nuclei, with a smaller centre on the dorsal side which affected the fifth root, were found. When we consider the vascular supply of these centres and the surrounding of these vessels with round cells, which for the most part are lymphatic in character, more light may be thrown on the proximate cause of the disease. We must also remember that leucocytes are also present, but the true plasma cell is always absent. Secondary degeneration is absent here also as in the spine. but the infiltration around the centre is absent, while the glia or ependyma cells are pigmented, which on the outer margin form a network. On the dorsal side the morbid changes were more extensive, but the disconnection was marked. In some of these centres a characteristic distinction of age could be discerned, the older by the perfect absence of the granular cells and cloudy appearance, and the later by the profusion of typical fatty granulations. This difference

could be observed in the Weigert preparations as easily as in Marchi's preparations. This same process of degeneration was as marked in the posterior roots, but in the pons the centres were smaller, particularly near the lower part. One point might be noticed that no pathological change could be observed in the facial centre; in the cortex, however, the changes were in two directions, the first in the usual form, the second an irregular thickening and diminution of the fibres without any real distinguishing centre. Those in their earlier stage had light and dark streaks in their substance.

When we consider the clinical picture of the disease the relatively acute form is dominant. but the premonitory signs are wanting. We find at the beginning the sensibility disturbed and anæsthesia present, which is an unusual circumstance in the disease. It was eminently progressive from the first, and in spite of the number of phenomena no remissions could be observed. The disturbance of the bladder is another symptom unusual in the disease, although the multiplicity of centres may have caused the disturbance, being located in the brain as well as the spinal cord. Charcot's symptomatic trias had only the nystagmus present

As the speech was in no way affected and the bulbar type scarcely noticeable, on the other hand, Strümpll's initial symptom of skin and cremaster reflex were distinctly pronounced.

Again from first to last the whole process was non-febrile, which is often met with in acute multiple sclerosis.

The same reasoning is true of the pathological anatomy and agrees with Marburg's investigations that a relation exists between the morbid no sign of glia formation was present, but a profusion of granular cells existed, which is an important factor to remember. Notwithstanding the wide area affected no trace of secondary degeneration was present, but in the older centres the characteristic signs of sclerosis were present, and not infrequently old and recent centres were indistinguishably united or difficult to isolate from the sclerotic and granular cells lying close to one another. This approximation has led to different theories, Marburg assuming that the process is a disseminated chronic encephalomyelitis, with which Müller concurs that the secondary multiple sclerosis cannot be distinguished from the primary lesion. Völsch and Schobs do not go so far as this, and think there

is a distinction, placing the sclerosis as an endogenous process peculiar to the disease by the deposition of glia or ependyma.

In the case just recorded we have seen that the vessels are relatively little affected, which is the usual history given in all acute multiple scleroses. Marburg makes use of this circumstance for the rapid growth of the glia. It is well known that in cicatrices after hæmorrhage or encephalitis the injuring of the walls of the vessels leads to a general ischæmia and thus hinders the active proliferation of the glia, which is never present in multiple sclerosis. In the latter the glia is injured, while the parenchyma and nerve sheaths are destroyed; the vessels are found to be intact and the nutrition of the parts maintained, which assist the rapid repair of the glia and form a substitute for the parenchyma. It must be always remembered that the axis cylinder

in the morbid centre is found intact, which may also assist in the increase of the glia and sub-

sequent repair.

As to the ætiology of the disease little can be said, and on it this case throws no light. Infection may have had some part in the origin of the morbid change, as the patient had erysipelas four years ago, and thus induced the morbid process by meta-infection.

# SOME ENLARGEMENTS OF THE KIDNEY.

By L. G. GUNN, M.D., F.R.C.S.I.,

Surgeon to the Adelaide Hospital.

GENTLEMEN,—I have to-day three cases that may be, with profit, seen together; all are renal cases; two present typical symptoms and are easy to diagnose; one is difficult, so difficult that the diagnosis was not correctly made until the case had been operated upon.

The first case is this girl, æt. 6. For five months past she has had attacks of pain in the right side of her abdomen; these attacks have been associated with vomiting and with frequency in passing water; she has lost flesh, looks pale, and has an elder brother who suffers from tuberculosis. Such

is her story, as related by her mother.

The child has been in hospital just ten days; during this time she has had two attacks of pain; one only lasted a few hours, the other, a severe one, lasted for nearly two days, and was associated

with a good deal of vomiting.

On admission her urine was examined-you see it was normal and free from any sediment; with the onset of each attack it became scanty, loaded with urates, and passed very often in small quantities. As each attack passed off, an abundant flow of pale-coloured urine took place; the frequency continued, but now with each act of micturition 6 to 8 ozs. of this pale urine were passed; it had a sp. gr. of 1008, and showed a faint trace of albumin. If you examine the child's abdomen now you can all readily feel a smooth tumour, lying in and below the position normally occupied by the right kidney. The tumour is painless; the tumour is smooth; it moves freely up and down with respiration; you cannot push it up under cover of the liver.

Examining this tumour during an attack, I noticed that it was painful; both lumbar group and the rectus muscle on the right side were rigid. In spite of this rigidity, it could be easily felt that the tumour had increased considerably in size; with the diminution of the attack and the profuse flow of urine the enlargement slowly subsided to

the size you see it to-day.

Such a train of symptoms pointed clearly to the condition here being intermittent hydronephrosis of the right kidney. What may cause this obstruc-tion to the flow of urine:—(a) Undue mobility of the kidney with kinking of the ureter; this can hardly be the case here, for there is no increased movement of the kidney. (b) The presence of a small calculus in the ureter; two excellent radio-graphs of the kidney and ureter, taken for me by Dr. Harvey, fail to show any shadow suggestive of a calculus. (c) Congenital narrowing of the ureter; this does not, as a rule, give rise to such markedly intermittent hydronephrosis; is usually bilateral, and shows itself much earlier in life. (d) Spasm of the ureter has been suggested in cases where no apparent mechanical obstruction can be found at the operation, or where there is

no faulty opening from the pelvis of the kidney into the ureter; sometimes the ureter enters the pelvis at an acute angle, making a somewhat valvular opening through which the urine may at

times fail to pass.

I suspect that one or other of these two latter to be the cause of the obstruction in this case. treatment: expose the kidney and ureter; obvious and well-marked obstruction exists, rectify this fault; if the cause of the obstruction is at all indefinite, then it is far better to remove the kidney. Plastic operations very frequently are followed by a urinary fistula, which can only be cured by a nephrectomy, and are seldom justifiable unless there is doubt as to the soundness of the remaining kidney. (a)

The second case I call your attention to is this young man. His symptoms are entirely bladder symptoms. He has pain on passing water, especially at the end of micturition; this pain is felt chiefly at the end of the penis, but it is a referred pain originating at the trigone, and felt, as it so commonly is, at the end of the penis. has frequency, both by night and by day. He passes water every hour, or oftener; if he tries to hold it longer acute pain comes on, compelling him to empty his bladder. This means acute inflammation in the bladder, or possibly ulceration. We look now at his urine and find it acid, sp. gr. 1015; it has a heavy deposit of pus; through this pus are streaks of blood. The microscopic examination of this sediment clears up the diagnosis of this case, for tubercle bacilli are found in numbers among the pus cells. Primary tubercle of the bladder hardly ever occurs; it is, however, often secondary to infection of other parts of the genitourinary tract. I have examined both testes, seminal vesicles and prostate, but in none have I found any sign of tuberculous infection. I want you all to palpate his kidneys; you will find his left kidney is more than double its normal size, but is mobile and entirely free from pain. He has had no symptom calling his attention to his kidney, and until it was discovered here the patient was quite unaware that he had anything wrong there. the bladder infection not occurred, the disease might have gone on for months without being recognised as a cause for his failing health. cystoscopic examination of the bladder revealed some tuberculous ulceration about the mouth of the left ureter; the ureter itself is gaping and retracted; from it pus is flowing. The first two appearances point to extensive mischief in the pelvis of the kidney. Two days ago I passed a catheter into the right ureter and drew off some 2 ozs. of urine; this proved to be normal in every respect. Under these circumstances the treatment indicated is removal of the infected kidney, to be followed by irrigation of the bladder twice daily with warm carbolic lotion of the strength of 1 in 150, and this treatment will be combined with small doses of tuberculin, about 1-2,000 mgr., given once a week. (b)

The third and last case is this woman, æt. 61. Three months ago she was sent in as an acute case of appendicitis. She had then a normal morning temperature, but each evening it rose to about 1010 She had constipation, a furred tongue, and both looked and felt very ill indeed. On examining her

<sup>(</sup>a) This child was operated on three days later. A hydronephrotic kidney was found, with no definite narrowing of the ureter at the point of apparent obstruction. Mr. Gunn accordingly removed the kidney. The child was sent home well three weeks later.

(b) The following week the kidney was removed without difficulty, and proved to be extensively infected with tubercle. Two months later the boy could hold his water for three hours and the urine was almost free from pus. No tubercle bacilli could be found.

abdomen we could both see and feel a swelling in the right side of the abdomen. The middle of this tumour was at the level of the umbilicus; it was very tender to handle, it could move a little both up and down and from side to side; its position and mobility made me think that this was not an appendix abscess, but a solid tumour of the upper part of the cæcum, probably a carcinoma. With enemata and rest in bed the tenderness gradually left the side and the temperature came down to normal; the size of the tumour did not diminish. Several examinations of her urine showed it to be quite normal. I could not satisfy myself that I felt the kidney on either side. I thought if the swelling was a carcinoma of the cæcum it might be removed, and with this idea opened her abdomen through this incision which you see here at the outer side of the sheath of the rectus. It was at once apparent that the growth was retro-peritoneal, the ascending colon passing in front of it, and being somewhat flattened by the pressure on its posterior wall. There had been, I suspect, some fæcal lodgment in the cæcum, and this had possibly caused the pain and fever. The tumour was then, as you can feel it now, about the size of a goose's egg, and somewhat the same shape, attached firmly to the lower pole of the kidney. It felt on palpation like a tense cyst with thick walls. Now, believe it is very rarely justifiable to remove one kidney without knowing the functional condition of the other, so in this case I closed the abdomen without doing anything further. It remained still uncertain what the nature of this tumour was. I have already shown you two enlarged kidneys, one hydronephrotic, the other tuberculous. Remember that her certainly neither of these. Remember that her urine contained no trace of pus, nor was there any history of hæmaturia; this is of great importance, for in the great majority of cases of solid tumour of the kidney, be it carcinoma, sarcoma, or adenoma, the first symptom is blood passing in the urine. The absence of hæmaturia was against this being a solid tumour. An X-ray photograph showed no shadows, so a stone could in all probability be excluded. The commoner cysts in connection with the kidney are hydatid, congenital cystic disease, and simple cysts. The urine was repeatedly examined for hydatid hooklets, but without finding any. In congenital cystic disease the whole kidney is affected, and the cysts are multiple. In this case the tumour was smooth on the surface, and probably single. We must, then, class this case as one of simple cyst growing from the lower end of the The question of treatment was a somekidney. what anxious one. The old lady, as you can see, is by no means strong, and nephrectomy is always a serious operation, with, in her case, a risk so definite that I would not advise her to have it done unless the removal of this tumour was of vital importance to her. A catheter passed into the right ureter showed that the two kidneys were acting equally, and that the urine was normal from both; this further confirmed me in the opinion that the tumour was a simple cystic one, and doing little or no damage to the patient. The woman has been under observation for the past three months; during this time she has put on nearly a stone in weight, and the tumour has not increased in size. I hope to keep her under observation for at least another three months, and if during this period the tumour becomes larger, or hæmaturia occurs, I shall advise the patient to have the tumour removed.

There are many lessons to be learned from these three cases. Possibly the most important is that extensive growth may take place in a kidney without any abnormality showing itself in the urine; a normal urine is therefore no proof that the patient has normal kidneys. Another important point is the freedom from pain. Both in cases 2 and 3 pain the freedom from pain. Both in Cases 2 and 3 pain the kidney there was no pain until the growth had infiltrated neighbouring tissues. The last point I would draw your attention to is, that the use of the ureteral catheter is essential for the successful treatment of such cases.

### **OPERATING THEATRES.**

GUY'S HOSPITAL

Congenital Enlargement of the Large Bowel—Removal of Volvulus of the Sigmoid, and Later Rectum.—Mr. W. Arbuthnot Lane operated on a girl, æt. 14, who had suffered from severe abdominal pain and constipation from birth, for which she had been treated medically by massage, etc. This condition became very critical in 1904, when he removed a huge volvulus of the sigmoid which filled and distended the abdomen. The junction was effected between the ends of the gut at the base of the volvulus by establishing direct continuity of the intestine. This corresponded to the upper part of the rectum. The rest of the large bowel was very dilated indeed.

The patient made excellent progress for a time, but

The patient made excellent progress for a time, but in February, 1908, owing to the pain, distension, and auto-intoxication, Mr. Lane opened the abdomen with the object of enlarging the junction which he thought might have contracted. The aperture of communication readily admitted three or four fingers, and it was obvious that the dilated large bowel was unable to evacuate its contents. There was no obstruction in the ordinary sense. By irrigation through a long tube, by massage and other means, some temporary alleviation of symptoms was obtained. In January, 1909, the auto-intoxication, pain, and distension had become so aggravated that he determined to remove the big bowel, although the condition of the patient appeared such as to render this operation exceedingly dangerous. On the other hand it was apparent that the end could not be long postponed unless the auto-intoxication was relieved. The child being under ether, about four pints of normal saline solution were introduced beneath the skin during the whole period of anæsthesia, such fluid being run in rapidly before the operation was commenced. The enormously distended large bowel, full of fæcal matter, was then gradually removed from the abdomen; the rectum was divided at its upper limit and closed, as was also the ileum, about four inches from its termination.

The end of the ileum was connected by a lateral anastomosis with the stump of the rectum, it being necessary to employ cleft palate needles and holder for the purpose, owing to the fact that only a small portion of the rectum covered by peritoneum was left after its ligature and closure. The child was much collapsed by the operation, but she improved slowly. On the fourth day her bowels acted, and continued to do so at intervals. Her pulse, which was very rapid before the operation, again became rapid, and continued so. She died after a prolonged struggle for life, lasting nineteen days.

Mr. Lane said that but for the use of large quantities of salt and water subcutaneously, both before and during the operation, it would have been impossible to have carried it through successfully owing to the very feeble condition of the patient. He had endeavoured to obtain from some relative or friend a direct transfusion of blood, but had been unsuccessful. It was very possible, he thought, that it might have saved the child's life. The advantages afforded by the immediate introduction of a large quantity of normal saline into the circulation, he pointed out, are most striking, the increase in the blood pressure reducing shock to a minimum, and preventing any vomiting. By the use of this procedure the risk attending the removal of the large bowel has been very materially reduced.

The explanation of the modus operandi of this is rendered perfectly clear by Dr. Crile's experiments on Though the condition of the large bowel in these cases differs altogether from those present in ordinary chronic intestinal stasis is that in the ormer there is considerable hypertrophy of the muscular coat of the dilated bowel, and that the bowel cannot be satisfactorily emptied by purges, yet the symptoms are very similar, namely, pain and auto-intoxication.

### TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

CLINICAL SECTION.

MEETING HELD FRIDAY, MAY 14TH, 1909.

The President, Sir THOMAS BARLOW, Bart., K.C.V.O., in the Chair.

Dr. T. STACEY WILSON exhibited three

COLOURED PROJECTION DRAWINGS OF THE BRAIN.

showing the relation which the internal structures would be seen to have to the convolutions, if the brain were transparent. These had been prepared by photographing serial sections, cut through a carefully graphing serial sections, cut through a carerumy hardened brain, and afterwards drawn to scale, and were designed to assist the surgeon in cerebral

Dr. ALEXANDER FLEMING gave a demonstration of a SIMPLE METHOD OF SERUM DIAGNOSIS OF SYPHILIS by the "Complement Deviation" Method.

This differed from Wassermann's original method in

the following respects:

(1) An alcoholic extract of normal heart muscle was used instead of a saline extract of syphilitic liver.

(2) The natural hæmolytic power of human serum for sheep's corpuscles was made use of, thus doing away with the necessity for the hæmolytic serum of a rabbit immunised against sheep's corpuscles and the guinea-pig's serum (complement).

(3) The amount of blood which can be collected in

an ordinary blood-capsule furnished an ample supply

of serum for the test.

As the outcome of the examination of a large number of cases of undoubted syphilis, both acquired and congenital, he had found that a positive result

was given in 96 per cent.
Dr. McIntosh asked how many controls had been used, as he was surprised at the high percentage of positive results obtained, which was higher than that obtained by Wassermann. He had himself found that, by the original method, a considerable number of cases of aortic aneurysm gave a positive result.

Dr. Fleming, in reply, stated that he had used over 300 controls, with a positive result in only 10 per cent. This was due to the fact that the blood of about 10 per cent. of normal individuals contained no hæmolytic power for sheep's corpuscles, a difficulty which might be got over by other means.

Dr. FREDERICK SPICER showed a case of

PARALYSIS OF THE RIGHT SPINAL ACCESSORY NERVE.

It was that of a traveller, æt. 32, who had always enjoyed good health until the middle of January last, when he complained of sore throat, weakness of voice, pains on the right side of the head, right shoulder and right arm. He was found to have paralysis of the right vocal cord, the right side of the soft palate, the right sterno-mastoid, and the right trapezius. There was very considerable wasting of the muscles, with marked drooping of the right shoulder. He had had influenza some four months previously; there was

no history of syphilis or injury.

Dr. F. E. BATTEN said that the patient showed one sign, which he thought threw some light on the nature of the case, namely, Argyll-Robertson pupils. He thought that the symptoms suggested an anomalous

of tabes.

Mr. Walter G. Spencer showed a

CASE AFTER REDUCTION OF AN OLD SUBCORACOID DISLOCA-TION OF THE RIGHT SHOULDER, COMPLICATED BY FRACTURE OF THE UPPER THIRD OF THE HUMERUS, BY EXCAVATING THE GLENOID CAVITY POSTERIOR INTERMUSCULAR INCISION.

An engineer, æt. 43, was riding a motor cycle when a collision occurred; he had received severe injuries—viz., fracture of the base of the skull with concussion, fractured ribs, dislocation of the head of the right humerus, oblique fracture of the upper third of the shaft of the right humerus, and widespread ecchy-moses about the right shoulder. The fracture of the humerus had slowly united with overlapping of the fragments to the extent of about two inches. When first seen, the humerus was fixed to the scapula, which could be moved very little, and the oblique union of the humerus was not firm. His arm could now be raised to the vertical without moving the scapula much more than normal. He could swing on a horizontal bar and use a 4 lb. dumb-bell. He had returned to work, and each week had shown increasing ability to carry out overhand movements.

Dr. Finzi showed a case of INOPERABLE RECURRENT SCIRRHUS OF THE BREAST UNDER TREATMENT BY RADIUM.

The growth had been present for eight years, and the breast had been removed three years ago. It had recurred, and been considerably improved by X-ray treatment, but, owing to the patient's failure to attend for some weeks, the growth had again become more rapid and extensive. From March 10th, 5 cgm. of radium filtered through a silver tube 0.6 mm. thickness and mm. thickness of india-rubber had been applied over the large mass for fifty-three hours, the position of the tube being altered once. On March 12th a dose of 41 hours was commenced in the axilla. The radium used was the pure bromide, and was contained in a little glass tube within the silver tube. The tumour by April 2nd, 1909, had almost disappeared except for a little thickening between the two places where the application had been made. This had proved to be a definite nodule, and a dose of 26 hours, with filters of 0.6 mm. silver and 1 mm. lead, and six hours with 0.6 mm. silver was given, starting on April 29th, 1909.

Also a case of EPITHELIOMA OF THE LOWER LIP UNDER TREATMENT BY RADIUM.

This had started as a pimple, which gradually got larger and became crusted over, and had been growing for 15 or 16 years. The rapidity of the growth had considerably increased for the last eight or ten months. There were enlarged glands under the jaw on both sides, but larger on the left than the right. Treatment by radium was started on March 31st. Epilation was noticed on the neck about April 20th, and on the left side of the upper lip on May 5th. Considerable improvement resulted both in the growth and the glands.

Mr. RICKMAN GODLEE asked whether in such cases

radium should be applied in a little tube or in various

appliances, as was being done in Paris.

Mr. WALTER G. SPENCER said that he hoped that the case of epithelioma of the tongue would receive ordinary surgical treatment. He had seen a somewhat similar case of epithelioma of the tongue which had been treated in Paris, and had developed very large cystic glands, encapsuled by malignant epitheliomatous growth. He considered that the treatment had made that case much worse.

Mr. GORDON WATSON said that the growth had certainly become smaller, as shown by careful measurements, and that now any operation would cause less mutilation than would have been necessary when the patient was first admitted to hospital.

Dr. A. HOWARD PIRIE said that if radium was spread

out too much it often lost its power.

Mr. PEARCE GOULD said that the exhibition of these cases was obviously only preliminary. They were both cases of a chronic type. He thought that Dr. Finzi had under-estimated the severity of the lesion in the second case. Any diminution in the prominence of the growth might be due to reduction in the lip around it. He did not think that there was any actual cicatrisation of the ulcer.

Dr. E. H. Shaw said that from the microscopical appearances he thought the treatment had caused no change in the carcinoma cells, but an increase in the round-celled exudation. There was no true scar formation on the surface of the ulcer.

Dr. Finzi, in reply, said that for deeper structures a small tube was necessary, but the radium could be more spread out for cutaneous cases. The decrease in the growth could not be due to diminution in the blood supply, because that was more than formerly. There was no true cicatrisation, but this did not occur with radium, for by it a film was produced and healing occurred underneath it.

Dr. Finzi also showed a case of

ARTHRITIS TREATED BY IODINE-LITHIUM IONISATION.
The patient was kicked on the left knee on May 8th,
1907. Synovitis followed. In July, 1908, the tissues
around the knee and the synovial membrane were much There was also considerable grating in the thickened. point, and he was unable to walk without a stick.

From Auust 7th to September 21st he had been treated
by iodine-lithium ionisation. This soon relieved the
pain and other symptoms. Before the treatment was
stopped the patient walked thirty miles, and had subsequently come in second in a running race. September 21st, 1908, there was great diminution in the thickening round the knee, and it was normal.

Mr. V. WARREN Low showed a case of

PNEUMOCOCCAL CYSTITIS AND ARTHRITIS. The patient was a young man, who had been admitted to hospital on December 15th, 1908. Cystoscopic examination had revealed the presence of cystitis, accompanied by numerous superficial ulcers and hæmorrhages of the bladder mucous membrane. A pure culture of pneumococcus had been obtained from the urine. On December 28th arthritis of the knee-joints developed, and the clear fluid which was removed yielded a pure culture of the same organism. Other joints which subsequently became affected were the right elbow, right fourth metacarpo-phalangeal, left right elbow, right fourth metacarpo-phalangeal, left elbow and left wrist. Only once was the temperature above 101° F., and the patient never appeared to be seriously ill. He was discharged to a convalescent home on February 24th, and had quite recovered. His treatment had been by vaccine therapy, using his own organism by urotropin, sammetto, and for a short time by Bier's treatment for the joints.

Mr. Sidney Boyd showed a case of SPRENGEL'S DEFORMITY OF THE SHOULDER AND HIRSCH-SPRUNG'S DISEASE, WITH DEFINITE RECTAL OBSTRUCTION.

The patient was a boy, æt. 9. Deformity of the left shoulder had been noticed since 3. The left scapula was higher and smaller than the right. It was freely movable, but movements of the shoulder-joint were somewhat limited. The boy had been constipated since birth, and on rectal examination a tight ring could be felt just above the sphincter. The colon was could be felt just above the sphincter. The colgreatly dilated, as shown by X-rays.

Dr. F. PARKES WEBER showed the case of a

WOMAN THREE YEARS AFTER OMENTOPEXY AND PERITONEAL DRAINAGE FOR CHRONIC ASCITES CONNECTED WITH HEPATIC CIRRHOSIS.

The liver was hard and large, reaching to the level of the umbilicus. Tapping had been required five times in the fourteen months preceding the operation. After the operation, which was performed on December 1st, 1905, the abdomen soon filled again and had to be tapped four times in the next three months. Two more operations had been performed, one to stitch more omentum to the abdominal wall, the other to give continuous drainage. The last tapping she had required was in January, 1907, and her general condition had greatly improved.

Dr. DE HAVILLAND HALL and Mr. W. E. SPENCER

showed a case of

SPLENECTOMY FOR SPLENIC ANÆMIA The patient was a girl, æt. 84, who was admitted to hospital for enlargement of the spleen and liver. had increased somewhat under observation until it reached forwards to the umbilicus and downwards to the iliac crest. There had been leucopenia. When exhibited the patient had greatly improved, and there was nothing noticeable except anæmia. The liver exhibited the patient had greatly minds. The liver was nothing noticeable except anæmia. The liver weighed 23 lb., and showed no microscopic change, except engorgement of the blood vessels.

HERNIA OF THE TIBIALIS ANTICUS MUSCLE. The patient, a man, æt. 40, had fallen and twisted his leg eight months ago, when a girder fell across his right foot. The rent in the deep fascia was due to irregular or sudden contraction of the subjacent muscle. The situation of the hernia would appear to

be unique.
Mr. W. H. BATTLE showed a case of

TUBERCULOUS KNEE, which had been dislocated, contracted and ankylosed. A Horfftiche's appliance had been used for three years, with the result that the dislocation had been overcome and fair movement obtained.

Dr. Poynton and Mr. Trotter showed a case of CARDIOLYSIS,

and read a paper on the subject. The patient, a boy, æt. 16, had been admitted into hospital under Sir Thomas Barlow, in August, 1908, with severe symptoms which were considered to be due to an adherent periwanter were considered to be the to an adherent peri-cardium, with mediastinitis, left pleurisy, and peri-hepatitis. He improved considerably after rest and was discharged, but was readmitted on September 21st, under Dr. Poynton, with the history that his symptoms had at once returned on leaving the hospital. At rest in bed he was much better, but on the slightest exertion ædema and breathlessness at once appeared. Cardiolysis was performed by Mr Trotter on October 5th, 1908. A semi-circular flap was marked out in the præcordial region, and was reflected up-wards. It included all the structures anterior to the ribs. The fourth and fifth ribs moved most with the cardiac movements, and between 3 and 4 inches of each were removed, the periosteum being left behind. The pericardium was found thickened and adherent to the chest wall over the region exposed. After removal of the ribs, the structures over the heart accommodated themselves far more easily to the cardiac movements. The flaps were replaced and the wound completely At the present time the operation had been justified by the result, for the patient could now go for a walk extending over half-an-hour, and in the evening there was only slight pitting over the ankles. The heart, liver, and spleen had all diminished in size.

The operation was first suggested by Brauer, and put into practice by Petersen in 1902. The idea was that in certain cases in which the heart is embarrassed by fixation to surrounding parts, a considerable amount of this overloading of the heart's action could be got rid of by rendering the præcordial part of the chest wall more flexible than normal by removing its bony and cartilaginous framework. No extensive separation of adhesions was suggested, and it is obvious that such would be dangerous. In the first obvious that such would be dangerous. place the subjects were unsuitable for anæsthetics, and the risk of tearing the heart or pleura was great. a review in 1908 a total of 17 cases had been collected; no death was recorded, and the results appeared to be very good. The most suitable cases were those in which the heart was just inadequate for active life. The chief difference of opinion lay in the advisability of removing the periosteum or allowing it to remain.

Dr. ALEXANDER MORISON said that Mr. Stabb had removed for him a rib over a sarcomatous growth to relieve pressure, leaving the periosteum, and the rib had been entirely renewed. Last year, in another case, parts of the fourth and fifth ribs and their periosteum had been removed for a ortic disease and hypertrophied The patient had been greatly relieved of pain. In a third case the operation had been done adherent pericardium, and again the periosteum had been removed. This had been very difficult, and the pleura was torn with the removal of each piece of rib. The patient had greatly improved, but died later of fresh pericarditis. He thought that it was almost inevitable that in the case shown the rib would again grow and the heart again be incarcerated.

The PRESIDENT said that there was no doubt but that the boy was much better. In such cases the jugular veins were often very large, and this had now disappeared.

Mr. RICKMAN GODLEE said it would be more important to remove the perichondrium than the periosteum.

Sir JOHN BROADBENT said that often in such cases

the right ventricle showed signs of failure which could not be relieved by this operation.

Dr. W. EWART said he would like to know whether the kidneys and liver showed improvement also, and suggested skilfully arranged physical treatment by rest

and exercise.

Mr. A. E. BARKER said that some form of cautery might be used to destroy the bone-forming capacity

of the periosteum.

Mr. TROTTER, in reply, said that improvement was continuously progressive. He thought that the amount of regeneration of bone depended much on the local conditions around the periosteum. He thought that Dr. Morison's cases went to show that the operation, where it had been removed, was very difficult, and that the pleura was often opened. In any case only a small posterior strip was left, much of which could be readily removed, but no formal attempt to remove it all should be made. The regeneration was usually only slight.

### EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

### MEETING HELD MAY 5TH, 1909.

The President, Dr. JAMES RITCHIE, in the Chair.

DR. BYROM BRAMWELL showed (1) A Case of Scleroderma of the Hands and Forearm under treatment with fibrolysin. The patient was by occupation a stonemason; in Dr. Bramwell's experience scleroderma was not uncommon in this trade. Under injections of fibrolysin considerable improvement had taken place. A notable point in connection with the use of the remedy was that the injections produced a febrile reaction, was that the injections produced a februe reaction, which appeared to be quite independent of any septic contamination. He had observed a similar reaction in some, but not all, other cases of disease treated with the drug. (2) A Case of functional nervous disease treated by isolation, Faradism, and the hypodermic injection of water. The patient was a child who had some months previously been bitten by a dog. The bits had healed perfectly but every day, at the hour at some months previously been bitten by a dog. The bite had healed perfectly, but every day, at the hour at which she had been bitten, the little girl complained of severe pain in the scar, and assumed the position she was in at the time she received the bite. She was told that she would soon be quite well, and that she would be isolated behind screens until her recovery. Under the influence of this energetic suggestion, and injections of water, isolation, and a milk diet the seizures very rapidly disappeared.

Dr. Walker showed (1) A Case of Acanthosis Nigricans in a woman. In many of the reported cases of this

in a woman. In many of the reported cases of this rare disease there was evidence of malignant disease of some of the internal organs. In the patient shown, however, this did not seem to be the case. The case was extremely typical of the condition; the occurrence was extremely typical of the condition; the occurrence of pigmentation very similar to that of Addison's disease was pointed out. (a) A Case of Pityriasis Rubra Pilaris. (3) A Case of Lichen Scrofulosorum. (4) A Case of Rapidly Advancing Tuberculous Ulceration of the Skin of the Thorax. (5) Cases of Lupus Treated by the Local Application of Tuberculin applied as a 5 per cent. ointment. This was rubbed in vigorously on four successive days and covered with a piece of lint. The result was a marked reaction, followed by lint. The result was a marked reaction, followed by selective sloughing of the tuberculous tissue. The results on the whole were extremely satisfactory. A point made was that in the case of small patches of lupus the reaction spread rather widely into the surrounding and apparently healthy skin, showing that it was also invaded by the process. This wide invasion of the surrounding skin appeared to be the principal reason why excision of a patch of lupus was so often

a failure.

Professor CAIRD showed (1) A man after ligature of the subclavian artery for axillary aneurysm. The third part of the subclavian was tied. At the operation it was remarked that on account of the upward displacement of the shoulder and the communicated pulsation it would not be difficult to mistake one of the cords of the brachial plexus for the artery. The only altera-tion in the circulation of the arm was a slight delay in the return of the normal colour when the parts were blanched by pressure.

(2) A patient after operation for internal strangulation. The symptoms were very acute, and simulated appendicitis, yet at the operation a band only partially constricting the small intestine was all that was found.

(3) A peculiar condition of the leg after passive congestion. The patient had had a condition of the left knee diagnosed as tuberculous, and for this Bier's treatment had been ordered. Anxious to carry out the treatment thoroughly, the patient had kept the bandage constantly applied for three days. constantly applied for three days. The result was to produce a permanent condition of elephantiasis. It was presumed to be due to some lymphatic obstruction, but the only definite change, apart from the elephantiasis,

the only definite change, apart from the elephantiasis, was a slight enlargement of the inguinal glands.

Mr. H. J. Stiles showed (1) A patient after pylorectomy for chronic ulcer of the stomach. Neither at the operation nor after the pyloric portion had been removed and split up was it possible to say whether the ulcer was simple or malignant. Microscopically the ulcer was found to have undergone malignant degeneration

(2) A patient after operation for extensive tuber-culous disease of the glands on both sides of the neck. Practically the whole of the glands had been cleared

Mr. STRUTHERS showed a baby, aged 17 months, which had received an injury to the head from a fall, and had been admitted to hospital in convulsions. On examination the child appeared to be dying; it was unconscious, with right-sided convulsions. A trephine opening was made over the left motor area and a good deal of cerebro-spinal fluid escaped. The fits at

once ceased, and the patient made a good recovery.

Mr. J. M. Cotterill demonstrated the use of
Burgess's instrument for irrigating the abdomen. The supposes a instrument for irrigating the abdomen. The instrument consists of a combined douche nozzle and syphon, and Mr. Cotterill commented on the easy way in which any part of the peritoneal cavity could be flushed out and left dry and clean by using it.

Mr. Cotterill also showed specimens of Hirschsprung's disease, tubercle and syphilis of the testicle, cancer of the penis, pigmented mole, tumour of the appendix etc.

appendix, etc.

Dr. ALEXANDER BRUCE showed (1) Multiple acute aortic aneurysms resulting from vegetative endarteritis.
(2) Acute hæmorrhage encephalitis. (3) Cystic tumour of the pituitary body which had caused bitemporal hemianopsia. (4) Large sarcoma of the pituitary

Mr. Stiles showed preparations removed from the two cases exhibited.

Dr. J. S. FRASER read a paper on the

HISTOLOGY OF ACCESSORY SINUS SUPPURATION. After describing the normal histology of the mucous membrane lining the cavities, he referred to the drain-age mechanism in normal and abnormal conditions, showing that the ciliary movements played an important part. He next discussed the histological changes in the mucous membrane in acute inflammatory conditions, in chronic catarrh, and in chronic suppuration, pointing out that the difference between chronic catarrh and suppuration was largely one of degree. Attention was also drawn to the relation between cedema of the various mucous membranes, polypoid swelling of the mucous membranes, and nasal polypi. In conclusion, stress was laid on the possibility of a more extended knowledge of the varying histological changes in such conditions affording a better basis for classification and treatment. The paper was illustrated by a number of lantern slides showing the points referred to.

### CORRESPONDENCE.

### FROM OUR SPECIAL CORRESPONDENTS ABROAD.

GERMANY.
Berlin, May 16th, 1909.

In the Fortschr. d. Medizin, 8/09, Dr. Burckhardt, of

Dresden, discussed the
TREATMENT OF UMBILICAL HERNIA BY MEANS OF
PARAFFIN WAX. When the hernia persists, he says, beyond the second

year it is likely to become permanent. Independent of operative closure, treatment by strips of adhesive plaster is very generally made use of. This has the disadvantage, however, that it frequently causes eczema, which makes the child cry, still more raising the intraabdominal pressure. The pad with the elastic bandage is just as difficult to bear, and must be made use of for a long time before the hernia is permanently cured. By injections of paraffin, on the other hand, there is a possibility of closing the hernial aperture in the course of a few days.

After most careful disinfection of the hands and of the parts to be treated, the hernia is raised by two fingers of the left hand. The contents then recede from lateral compression. The right hand now introduces the needle, the tip of which is flexed, and has its exit opening on the side opposite to the flexure. It is introduced in such a way that the point is free in the hernial sac. Three to 4 cm. of paraffin are now introduced at a temperature of 65° C., when, the pressure of the left hand is relaxed so that the hernia feels to be as full as it was before. The part is now to be sprayed with ethyl chloride, and the needle withdrawn. The point of injection is now to be covered with a gauze pad, and fastened on with plaster. A circular plaster bandage kept on for a week ensures success. There is now a paraffin cap within the sac, which has solidified under the ether, by the bandage it is pressed into the shape of a plate, and completely prevents any further escape of the bowel. The irritation it now content leads to inflammators adhesion at the nack of causes leads to inflammatory adhesion at the neck of the sac.

On first attempts the mistake is often made of using too much paraffin, which makes the pad large and unsightly. The limit to this method is that the neck of the sac must not be more than r cm. in diameter; when larger than this, several sittings will be necessary to form a pad sufficiently large to keep back the bowel; this is especially the case when the rupture is associated with diastasis of the linea alba. No untoward complications have ever been met with in carrying out the procedure; if any paraffin escapes into the abdominal cavity, it solidifies quickly and does no harm. Only the so-called hard paraffin with a melting point of 54 c. should be made use of; it should be sterilised before use by being boiled in a closed vessel. The right temperature can be got by means of a dip thermometer, and the syringe and cannula must be kept in almost boiling water before use in order to prevent the sac must not be more than I cm. in diameter; when in almost boiling water before use in order to prevent solidification before the wax can be injected. Rubber coverings over the syringe do not do much good but prevent asepsis.

prevent asepsis.

The writer always operated in this way unless the walls of the hernia were too rigid and cicatricial, to allow fluid paraffin to be easily introduced. In such cases he uses a syringe with a rotatory piston, which will force out the paraffin under pressure, in the same way as ointment is forced out of a collapsible tube.

Children here the treatment ways wall

Children bore the treatment very well.

Soft paraffin, often mixed with vaseline, is dangerous on account of the liability to embolism. It also becomes absorbed, and is liable to wander, and act as a foreign body.

When hard paraffin is used, organisation takes place in the sense that the pad becomes surrounded by a hard mass of connective tissue. From this a largemeshed network of connective tissue partly divides the pad, but holds it firmly in place.

During the period of four years he failed to notice

any change in the pads so introduced.

any cnange in the pags so introduced.

PROTECTION FROM SMALL-POX IN PRUSSIA.

A note has recently been issued by the Prussian Ministry to the proprietors of warehouses in which rags are sorted and dealt with. It acknowledges that it would be difficult to carry out a wholesale revaccination order; that in the case of rags collected inland there would be very little danger of infection from them, that in the cases in which the rags come from a foreign source, and especially when they come from a foreign source, and especially when they come from the interior of Russia, there is considerable danger that those who are compelled to handle them may contract infection. This being so, it calls upon those superintending such warehouses to instruct their employees in the matter in a friendly way and to urge upon them the importance of re-vaccination. In cases

in which infection has been distinctly traceable to handling such rags the law with regard to such cases will be strictly carried out.

### AUSTRIA.

Vienna, May 16th, 1909.

ENDONASAL OPERATION FOR HYPOPHYSIS CEREBRI. At the Gelsellschaft der Aerzte, Hirsch gave a description of an operation which he recommends for the removal of a morbid pituitary body. After anæsthetising the internal parts of the nose he removes the middle turbinated bone, and then allows the part to rest a few days. After a short period he anæsthetises again and removes the posterior part of the ethmoid bone. Again a pause is made, with a longer interval before commencing the third time, on which occasion he removes the anterior wall of the pterygoid bone, making another pause before he opens the dura mater

and removes the morbid growth.

Hajek doubted the advantages to be obtained from this method, as the nose would tend to collapse after the operation. Again, the *technique* was so elaborate and the operation so protracted, while the access was so natter in the nasal channel that he doubted whether the operation could be satisfactorily performed at such a distance from the exterior. He considered this surgical method too circuitous and dangerous for general practice. Ranzi thought the objections covered the advantages, as the sella in the morbid condition lay further off than in the normal state, thus adding to the further off than in the normal state, thus adding to the difficulty, while the danger of meningitis was certainly greater. The cosmetic advantage in the endonasal operation was very questionable when compared with Hochenegg's method, which always gave satisfaction. Tandler asked if the optic nerve was not in greater danger, while Schüller commended this operation, as he had examined many of the results with the Röntgen had examined many of the results with the Röntgen rays and concluded they were more favourable than others. Moszowitz and others expressed their fear of inducing meningitis more readily by infection. Hirsch, in his reply, thought Hajek's fears were unfounded, as the opening he made into the base of the brain was very small, but sufficient to remove the hypophysis; but a small, but sufficient to remove the hypophysis; but a partial removal he found always gave favourable results. Again, the stage method had the advantage of not reducing the patient, as the bleeding was very slight and easily controlled. The fear of meningitis was no greater than in other operations. The danger of wounding the optic nerve was always great, under any circumstances, especially when the septum was thickened, but no greater than other surgical operations in rhinology. His statistics of infecting the meninges in rhinology. His statistics of infecting the meninges through the lamina cribrosa were no higher than other operations.

LUXATIO FEMORIS CENTRALIS. LUXATIO FEMORIS CENTRALIS.

Handek presented a case which required the Röntgen rays for diagnosis. The patient fell seven months ago from a window he was cleaning. After the accident the left side of the chest, left forearm, and left hip were injured, which kept him in bed three months. He had no great pain, but after getting out of bed he had a limp, caused by a shortening of 4 ctms. in the left leg. Measurement gave a shortening of 1 ctm. in the Rosa-Nelaton line, and 2 ctms. between symphysis and trochanter. Pressure on the trochanter major gave and trochanter. Pressure on the trochanter major gave no pain, and the leg was slightly adducted. The rays showed that the femur was intact, but the acetabulum had been injured and allowed the head of the bone to move forward and form a new depression, round which periosteum and bony structure had formed. It appears that the ascending ramus of the pubic bone had been fractured by the fall, which allowed the head of the femur to move forward into the fractured cavity.

### HUNGARY.

Budapest, May 16th, 1909.

AT the recent meeting of the Nagyvárad Medical Society, Dr. Révész Vilmos read a paper on the EXCRETION OF SALTS IN NEPHRITIS.

He said that if a healthy person is kept on a uniform diet for several weeks and then a certain amount of chlorides, phosphates and sulphates be given, these salts may be excreted in twenty-four to forty-eight hours, but occasionally the excretion may begin only in twenty-four to forty-eight hours, and last for three days more, even where there is no nephritis. He has studied this fact with regard to nephritis, and found that in cases without cedema, two types may be recognised as far as the chlorides are concerned. In one, the ingestion of a medium quantity of salt is followed by diuresis with a diminished percentage, in the other the percentage is constant and not influenced by the amount of urine. In uncompensated nephritis with cedema the percentage is frequently diminished if salt is given. There seems to be a distinct antagonism between chlorides and phosphates, for the latter are excreted most freely where the retention of chlorides in the system is greatest and vice versa. The same holds true for the sulphates. From a prognostic point of view, an increased excretion of chlorides in nephritis, after a period of retention, is a favourable sign, hence a diminished excretion, an unfavourable one. A prolonged increased discharge of phosphates will speak for a retention of chlorides. A drug, such as diuretin, which would wash the chlorides out of the system, would have a favourable influence upon the cedema were it not for the injurious effect upon the renal epithelium. Heart tonics are in place, as they help unloading the system of salt, but salt itself should be restricted in the diet. The so-called thirst cures do not rest upon a sound basis, since the retention of salt, and not that of water, is the primary cause of cedema. If saline intravenous or subcutaneous infusions should be necessary, in the course of the disease, they should be hypotonic, that is, should contain less than o.gr per cent. of salt.

The Biological Function of Calcium.

Dr. Mechwart found, in an investigation of the relation with calcium bears to the enzymotic process that results in the coagulation of the blood, that calcium is present in the ionic state, and that the amount of calcium-ion sufficient to bring about coagulation is very small, much less than the total quantity of calcium normally present in the blood. This hypothesis explains rationally a large number of phenomena relating to blood coagulation, namely, as follows:—(1) All the physical causes that diminish the degree of ionisation can produce incoagulability (cold, great molecular concentration). (2) All those reagents which, like the oxalates, fluorides, and alkaline carbonates, prevent coagulation by combining with the calcium in the blood, produce this result, when present even in very small doses. Upon the basis of his researches, Dr. Mechwart concludes that the coagulation of the blood requires the presence of ca-ion, whose concentration may vary between wide limits; this concentration has a minimum and maximum, below and above which respectively the blood remains indefinitely in a liquid state. The blood will not coagulate if by means of physical or chemical reagents the ca-ion is made to go beyond the above limits.

Asepsis in Catheterisation.

Dr. Kasper recommends an ideal lubricant for catheters and sounds. This consists of a mixture of glycerin, water, and tragacanth, together with mercury oxy-cyanate, I in 500. This does not irritate the urethra, renders the instruments very smooth and slippery, is readily soluble in water, and dissolves as soon as the instrument is inserted into the bladder, without obscuring the view through the cystoscope. In place of boric acid for washing out the bladder, he prefers mercury oxy-cyanate, I in 5,000. This is non-irritating, does not injure the instruments, and although not a strong antiseptic, is yet sufficient to inhibit the growth of microbes. His method is as sponges dipped in tincture of green soap, using each one for a minute. The instrument is then wrapped in a compress impregnated with the same material and kept in this until needed. Whatever parts can be removed are boiled for five minutes.

### FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

ABERDEEN ROYAL INFIRMARY.—Dr. Angus Fraser, Physician to the Royal Infirmary, has intimated to the

directors his resignation, after a period of office extending to 38 years. In recognition of his services the directors have appointed him a Consulting Physician to the institution.

A New Species of Strophanthus.—Sir Thomas Fraser and Dr. Mackenzie have recently communicated to the Royal Society of Edinburgh some interesting researches on a new species of strophanthus strophanthus sarmentosus, used, like so many other plants of the same genus, as an arrow poison in Africa. The general action of the new drug on the circulatory organs is much the same as that of the official strophanthus hispidus.

THE SIDLAW SANATORIUM.—From time to time within the past few months notices have appeared in the Press relative to the proposed municipalisation of the Sidlaw Sanatorium for Consumption, an institution near Dundee containing 40 beds and maintained Ly public subscription. It now appears, however, as though the proposed scheme has fallen through just at the moment when it seemed about to culminate in success. In the scheme proposed by the Medical Officer of Health, and taken up with energy by the Public Health Committee, there was to be a threefold campaign against tuberculesis—compulsary potified campaign against tuberculosis—compulsory notifica-tion, sanatorium treatment of curable cases, and segregation of the incurable. It seems that in Dundee the public health rate falls entirely on occupiers, not on owners, of property, and to meet the cost of upkeep of the sanatorium a special sanatorium rate of 2d. per £ was proposel to be levied, falling equally on owner and occupier. Arrangements for the transfer of the sanatorium were almost complete when so strong an agitation was raised by those who considered their interests affected by the incidence of the sanatorium rate, that the Town Council rescinded its resolution and cancelled the agreement. If, as has been stated, this is due entirely to a dislike of the owners of property to bear their share of a new development of the public health rate, it is very regrettable from the point of view of the general community. It must not, how-ever, be forgotten that many of those who are most active in fighting against the ravages of tuberculosis still hold that the duty of the community is limited to prevention of the disease by notification, disinfection and segregation, and that the idea of its attempting to cure early cases opens up a very wide field of possible responsibility.

### BELFAST.

PHARMACY ACT PROSECUTIONS.—Three Belfast druggists were last week fined for compounding and retailing medical prescriptions, without being properly qualified. In one case an interesting point to medical men arose, and that was, what constituted a prescription? In the case in point the prescription was written on a paper with a printed heading, containing the doctor's name, and it was signed with his initials, but some doubt was expressed as to whether in the eyes of the law such a document is a medical prescription, if it is not signed with the full name.

BELFAST HEALTH JOURNAL.—It is nearly twenty years since Dr. Henry O'Neill published the first number of the Belfast Health Journal, a periodical designed to castigate evil-doers in sanitary matters, and teach the ignorant the way of health and happiness. Since then the journal has appeared with as much regularity as a volcanic eruption. The proprietor and editor has lately made school sanitation his special hobby, and in his latest issue he deals with the defects of the Irish schools in a very thorough manner. It is a fine subject for an ardent reformer, and Dr. O'Neill has always been a hard hitter. Now that he is qualified as a barrister as well as a medical man, his blows are no less vigorous, and better aimed than ever Photographs both of new and old schools make the matter plain to the man in the street and his wife in the kitchen, for whom the publication is specially designed, and there can be little doubt that its effect will be good. Country as well as city schools are dealt with.

GOLF.—A very handsome cup has been made to the order of the golfing members of the Ulster Medical Society by Messrs. Sharman Neill and Co., of Belfast,

on the model of the celebrated Ardagh Cup, perhaps the finest specimen of old Irish silver work extant, which is now in the Kildare Street Museum, Dublin. This cup is to be known as the "Belfast Cup," and is to be offered for competition to medical golfers during the Belfast meeting of the British Medical Association next July. It will be played for at Newcastle, Co. Down, on Friday, July 30th, by bogey score.

### LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

### "EMPTY POCKETS."

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—When I penned the letter which you honour me by printing to-day under the above heading, I did not imagine that in the Times of this date there would have been afforded some more illustrations of the literally shameful position before the law which our profession holds in comparison with dentistry, and with veterinary surgery. This position is entirely due with veterinary surgery. This position is entirely due to the apathy of our leaders, and of the organised bodies, like the British Medical Association and medical defence societies, which ostensibly exist to protect the honour, and promote the interests of our profession. It has been pointed out in your pages more than once by a well-known writer on this subject, that, from the sordid point of view, the practice of medicine and surgery by unqualified pretenders, including the vast amount that is carried on under the cloak of the traffic in worthless nostrums and bogus apparatus, does not constitute entirely an injury to the legitimate practitioner. The damage to the public health to which fraudulent practice of all kinds gives rise makes in the end much work for qualified men. But the fact that doctors have no protection by the State is extremely derogatory to them as a body; and there can be no doubt that the respect of the mass of the public for them would be greatly increased if the Government would practically demonstrate the fact that they are worthy of due recognition and consideration. Neither the public nor our statesmen are cognisant of the facts of the case—these will never be authoritatively set forth until the whole matter has been gone into before an unimpeachable tribunal, a Royal Commission, such as you have so ably and persistently advocated. The cases to which I allude above were heard in different London police courts on May 11th. In one case, at Lambeth, a man was fined £10 and two guineas costs; in a second case, at North London, a man was fined £20 and five guineas costs for the offence of using a description implying that he was qualified to practice dentistry. In neither case did it appear that a professional title had been employed. Such convictions are impossible under the Medical Acts. Not only may unqualified pretenders use words implying that they are qualified, but they can with impunity adopt bogus titles, and employ phraseology in their advertisements sufficient to lead even the educated public to accept them as distinguished members of the medical profession. This state of things is, of course, not the sole cause of the emptiness of the poor practitioners' pockets, but it forms a potent factor in the causation of this deplorable condition.

I am, Sir, yours truly,
AN OBSCURE PRACTITIONER.

May 12th.

GENERAL PRACTITIONERS AND MIDWIVES. To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,-I cannot allow Dr. Griffith's letters to pass without comment. He has strayed right away from the points which were originally under discussion. He says that we do not call the St. John's Ambulance trained "quacks." I quite agree with this remark; but let us not forget that the Ambulance man gives his services in the event of an emergency, and then the patient is taken care of by a duly qualified medical man. The temporary nature of the treatment and the

necessity of calling in a medical man as soon as possible are impressed upon all Ambulance candidates. Let us hope, for the sake of our profession and also for the sake of the natives that the day is and also for the sake of the harves that the day is not very far distant when we shall be able to abolish the Zenana Medical Mission College with its shortened curriculum, and we shall be able to send to the natives as skilled and well qualified practitioners as we have at home. I do not wish to disparage the good work of this medical college, but the sooner we can replace it by sending out to the mission field duly qualified medical men and women the better it will be for all concerned.

I am, Sir, yours truly, S. J. Ross.

Monkhams, Bedford. May 12th, 1909.

THE LATE SIR WM. T. GAIRDNER, M.D., F.R.S. To the Editor of THE MEDICAL PRESS AND CIRCULAR.

Sir,-In response to the wishes of Lady Gairdner and her family, I have undertaken to edit the medical and scientific papers and articles of the late Sir William Tennant Gairdner, and to preface the collection with a biography.

In order to render the work as worthy as possible of the memory of the late professor, I am desirous of enlisting the sympathy and help of his friends. I venture, therefore, to request through your columns that anyone who has in his possession any letters or other literary remains of Sir William Gairdner will be so kind as to communicate with me.

I am, Sir, yours truly, G. A. Gibson, M.D.

3, Drumsheugh Gardens, Edinburgh. May 12th, 1909.

AN URGENT APPEAL FOR ASSISTANCE. To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,-We desire to bring under the notice of your readers the case of a registered medical practitioner of many years standing, and in good repute in Dublin. Owing to circumstances of a family nature, not in the least degree reflecting on his character or on that of any member of his family, and to his indifferent state of health of late, he is in urgent want of pecuniary help to enable him to maintain his position. We therefore venture to appeal for that assistance to the members of his own profession, who are always

willing to help their brother practitioners.

Any of the under-signed will be glad to receive any donations that may be kindly sent in response to this

urgent appeal.

We are, Sir, yours truly,

Andrew J. Horne,
Pres. Royal College of Physicians of Ireland. JOHN LENTAIGNE,

President Royal College of Surgeons,
JOHN W. MOORE, M.A., M.D., D.Sc., F.R.C.P.I.,
40 Fitzwilliam Square, Dublin.
CHARLES A. CAMERON, Kt.,
51 Pembroke Road, Dublin.

May 11th, 1909.

THE ADMINISTRATION OF ANÆSTHETICS. To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The letter of Dr. Kirkpatrick on the above subject in your last issue contains an argument which has now been trotted out many times in the past few months without its unsoundness being discovered. He says: "The number of deaths recorded as occurring during the administration of anæsthetics by qualified dentists compares, in every wav. most favourably with the number recorded as occurring during the adminis-tration by medical men." It would be strange indeed if the administration of an anæsthetic for the extraction of a tooth were accompanied by as grave a risk as that for, let us say, a laparotomy. Yet this is the comparison relied on by Dr. Kirkpatrick and many others who have written about the position of dentists in regard to the administration of anæsthetics. If anything is to be proved as the relative capacities of

medical men and dentists to administer anæsthetics, then the comparison must be between operations of a similar character in each case. It can hardly be maintained that of the fatalities which occur in dental work more in proportion have occurred in the hands of medical men than in the hands of dentists. in the hands of domining I am, Sir, yours truly,

MEDICUS.

### **OBITUARY.**

ERNEST ALFRED SNAPE, M.D. BRUSSELS. We regret to announce the premature death of Dr. Ernest Alfred Snape, at his residence in Welbeck Street, London. The cause of death was heart failure Street, London. The cause of death was heart failure following an operation for appendicitis by Sir Watson Cheyne. The eldest son of the late Rev. A. Snape, Vicar of Bury St. Edmunds, he was educated at Charing Cross Hospital, University College, London, and the University of Brussels, where he took the M.D. degree in 1893. Dr. Snape was author, with Dr. W. K. Sibley, of a report on Special Hospitals in London with reference to the custom of the street. with reference to the question of hospital abuse. His genial nature made him the centre of a large circle of professional and social friends, to whom his sudden death will be a source of deep and heartfelt regret. At the time of his death he had built up a large and lucrative private practice. Amongst other posts he held that of Honorary Physician to the Cripples' Home, St. Marylebone, and the Governesses' Benevolent Institution.

DR. WHITTLE, OF BRIGHTON.

THE death of this gentleman, which occurred last week, at Las Palmas, Canary Islands, was not unexpected; his health had been failing for some time, pected; his health had been failing for some time, and the visit to the Sunny South was undertaken in consequence. Dr. Whittle, who for the past 33 years had resided at Brighton and was a prominent practitioner of the town, had retired from active practice for some time past. He obtained the Membership of the Royal College of Surgeons, England, in 1873, and the Fellowship in 1876. He was also a graduate of London University, taking the M.D. Degree in 1882. He was elected President of the Brighton Medico-Chirurgical Society in 1801, and was also a hon-Chirurgical Society in 1891, and was also a hon, physician at the Brighton and Hove Dispensary and formerly house surgeon to the Brighton Hospital for Women and Children.

### SPECIAL ARTICLES.

### INTERNATIONAL MEDICAL TEMPERANCE APPEAL.

IT is proposed to present at the Twelfth International Congress on Alcoholism, to be held in July, 1909, in London, an International Medical Temperance Appeal to the rulers, teachers, and clergy of all nations.

Many of the Continental countries are already well represented by signatories. It is hoped that Great Britain and Ireland may not be behindhand in the matter. It is asked, therefore, that all who are willing to sign will intimate the fact immediately to Mr. W. McAdam Eccles, M.S., 124 Harley Street, London, W.

APPEAL TO THE MEDICAL PROFESSION OF ALL NATIONALITIES.

The International Union of Medical Abstainers, founded at the Eleventh International Congress against Alcoholism, held at Stockholm in 1907, invites medical men of all nationalities to unite for common action to break the bonds of alcoholism. This appeal is based upon the following main considerations:—

(1) Many of the physical ills we have to bear are, and will be, the result of the action of alcohol taken in

the form of a beverage.

(2) To the medical profession falls the special duty

of instructing people on these matters.

(3) The consequences of the continued use of alcohol, as shown by the history of the human race, are always the same; demoralisation, degeneration of individuals, and decadence of nations

(4) Spirituous drinks of any kind are unnecessary for the healthy individual; a desire for them exists only where it has been created artificially.

(5) All normal organisms perform their various functions better without alcohol, which is specially

dangerous to young or growing tissues.

(6) For the welfare and preservation of future generations it is necessary to discontinue the use of alcoholic beverages, as only by widespread abstinence can alcoholism with its consequences be met and restricted.

On these grounds we members of the International Union of Medical Abstainers call upon our Medical brethren of all lands to unite with us in the struggle against alcoholism and to sign the following appeal:

APPEAL FROM THE PHYSICIANS OF ALL COUNTRIES
To all Rulers, Governments, Representative
Assemblies, to all tutors, teachers, clergymen, and to all who have at heart the welfare of our race and of

We members of the medical profession, believing that by our studies and opportunities of recognising and estimating the nature and action of alcoholic beverages, we are qualified to offer an opinion, affirm it as our strong conviction that these beverages are not only unnecessary, but are extremely injurious, and that the evils which arise and are ever breaking out from the consumption of alcoholic beverages can, and must be, eradicated and prevented. We believe that young people especially should receive careful and as full instruction as possible, and should be trained by example, as well as protected by law, to abstain from the consumption of alcoholic beverages.

We are fully convinced that some such step must be taken in order to create a sober world and to promote and insure the happiness, welfare, and progress of the

human race.

### ADULTERATION OF DISINFECTANTS.

In the House of Commons, recently, the President of the Local Government Board was asked by Mr. J. D. Rees whether, in view of the promise made behim in 1907, and the statement of Professor Hewlett in the recent Milroy lectures at the Royal College of Physicians, that, in 1905, 1906, and 1907, 28,000 gals., 37,000 gals., and 66,000 gals. of liquid were sold as disinfectants under the Privy Council Order of 1900, whereby grocers and oil and colourmen are prohibited from selling disinfectants containing more than 3 per cent. of carbolic acid (the result of which was to place a premium on adulteration and inefficiency), he would state what steps he proposed taking to remedy the evil.

Mr. C. F. Masterman, who replied, said that at

present he is not empowered to fix standards of disinfectants, and it did not appear that he could usefully take action in the matter. He added that there is little public advantage in the domestic use of disinfectants as deodorants. Where they are used to remove infection they are commonly employed under the advice of a Medical Officer of Health or other medical man, who might be trusted to order disinfectants which are

Mr. Rees asked the hon, gentleman whether he was not aware of the fact that in other Government departments a standard was enforced by administrative custom. Such an extension of the standard would be an advantage to the public health.

No answer was returned.

The promise made by the President of the Local Government Board, to which Mr. Rees referred, was to the effect that if it could be shown that people of the poorer classes were in the habit of using deodorants as disinfectants, and not merely as deodorants, he would consider what steps could be taken to ensure that preparations sold as disinfectants should possess some actual disinfective action. The figures quoted by Mr. Rees, which represent the sale of "disinfectants" in small quantities to poor people, are ample evidence that there is a large demand for disinfectants. Mr. Masterman, it will be noted, is of the opinion that there is little advantage in the domestic use of disinfectants as deodorants, but no one, I imagine, would deny that if deodorants as such be used at all, it would be very much to the public advantage that they should possess disinfective efficiency.

In all Government departments, with the solitary exception of the Board of Agriculture, a guarantee is required that the disinfectants used by the department shall have a certain stated efficiency. If this precaution be necessary in the circumstances in which disinfectants bought by a Government department would commonly be used, how much more necessary must it be when they are to be used in the homes of

the poor.

Mr. Masterman's contention that where disinfectants are used domestically for the removal of infection they are commonly employed under the advice of a Medical Officer of Health or other medical man, "who might be trusted to order disinfectants which are efficient," is unsound. Apart from the curious fact that obsolete disinfectants and methods of disinfection are still not uncommonly advccated by otherwise highly qualified medical men—as witness the prescription by an eminent Irish official of sulphurous fumigation in tuberculosis the practitioner would, in the ordinary course, probably recommend or order the use of "a disinfectant" without specifying what the disinfectant should be. The result, at any rate, in the humbler class of houses, would be that one of the useless preparations sold by grocers and oil and colourmen would be used.

The remedy is very simple. Under the Privy Council Order of 1900, the grocer and oil and colourman is prohibited from selling disinfectants containing more than 3 per cent. of carbolic acid, and, as a consequence, the preparations sold as disinfectants cannot possibly possess any disinfective efficiency. The rescindment of this Order, and the substitution of one requiring that all disinfectants sold as such shall possess a guaranteed minimum carbolic acid co-efficient, would not only remove the evil which now exists, but would ensure that preparations sold as disinfectants would be capable of efficient disinfection. This surely would be greatly

to the public advantage.

### MILITARY & NAVAL MEDICAL NOTES.

A VERY stupid and useless system of competitive hospital diets, says the Military Mail, of April 30th last, has sprung up in Aldershot of publishing in "command orders" the cost per head for the subsistence of the patients in the various military hospitals in the command. It is obvious, says our military contemporary, that the comparison is being made to force the hands of the medical officers in charge to keep the cost

per head down to the lowest limit, a system which may have grave results on the health of the patients should those in authority insist on making unfavourable comparisons, and so compel those in charge to economise at the expense of the patients' food. In this monthly so published the Cambridge Hospital is shown as having spent £1 1s. 5d. per head per month for the sustenance of its patients, whilst the Bordon Hospital spent only 12s. 8d., and the Longmore Hospital spent only 12s. pital, only three miles away, spent £,2 7s. 8d. The difference in the amounts can no doubt be traced to the peculiar conditions under which each hospital exists, and the difference in the class of patients, and is capable of perfectly fair explanation. So no good can accrue from publishing these comparisons without also giving the special reasons, known to the officials, why the cost varies so greatly with the different hospitals. It is well-known, we should add, that the Cambridge Hospital at Aldershot generally treats the severest cases. The arrangement is somewhat unsound.

THE Naval and Military Record, of April 29th, has a letter headed "Sisters in R.N. Hospitals," which gives support to the quotations we gave in our issue of May 5th on the same subject. It looks as if something is defective in the Regulations for Sisters in Royal Naval Hospitals.

Another Naval medical subject attracting attention is the poor rate of pay and slackness of promotion in the sick berth staff of Naval hospitals which a Naval surgeon has written up lately.

INVALIDS disembarked in London from stations abroad are in future to be sent direct to the Royal Naval Hospital, Chatham, instead of to the ports to which they belong, as has hitherto been done. The Royal Naval Hospital at Chatham is a large and important charge, and has for years past been administered by a Deputy Inspector-General of Hospitals, R.N., and also an Inspector-General.

HIS EXCELLENCY THE COMMANDER-IN-CHIEF IN INDIA, as President of the Central Executive Committee of the St. John's Ambulance Association, has been pleased to appoint Major R. J. Blackham, R.A.M.C., to be Honorary Secretary of the Indian branch, in succession to Major A. M. Cameron, who is shortly proceeding to England.

THE work of disinfecting the barracks occupied by the troops of the British Army of occupation in the Citadel at Cairo, Egypt, has now been finished. The work has been in hand over a month, during which soo rooms were done, and, as might be expected, thousands of bugs, cockroaches, fleas and other pests were exterminated. In addition to these, in one store alone 61 rats were found, suffocated by the gas used for disinfection. The military authorities are to be commended for adopting this very successful system of disinfection.

A TREASURY White Paper shows that recruiting for the Army Service Corps, Royal Army Medical Corps, and Special Reserve, with drill on enlistment, has brought about an excess of expenditure of £30,000.

THE unusual sight of a parade of mounted nurses of the First Aid Yeomanry Corps in Regent's Park riding school caused great interest and excitement. First Aid Nursing Yeomanry Corps is not yet officially recognised.

### REVIEWS OF BOOKS.

OPERATIONS ON THE UTERUS AND PERINÆUM. (a)

This work deals with a limited portion of gynæcology, but in a manner which renders it most

(a) "Operations upon the Uterus, Perinsum, and Round Ligamenta."
By W. T. Stewart M'Kay, M.B., M.Ch., B.Sc., Senior Surgeon
Lewisham Hospital for Woman and Children, Sydney. Pp. 470 with
148 photographs. London: Ballilere, Tindall and Cox. 1909. Price 21s.

useful and explaint. The author has undertaken the difficult task of explaining the method of repairing the perinæum, and has adopted illustrations as the chief method of explaining the operations, with a short description in the letter-press. He describes the operations which he has found most useful in his own practice, and carefully points out the limitations of each, and indicates the class of cases in which the different operations may be expected to effect cures. The work commences with the consideration of the muscular and fascial constituents of the pelvic floor, and a description of the action of the different muscles in their normal state and of what occurs when rupture takes place, showing how distension of the perinæum is caused by the retraction of the muscles or the loss of the proper points of attachment from which they should act so as to resist the intra-abdominal pressure. The importance of both muscle and fascia in the formation of the pelvic diaphragm is impressed, and it is shown that the levatores ani are the principal structure of the diaphragm, but requiring for the maintenance of its integrity the support of the fasciæ. Tears of the perinæum are divided into three classes, and the author points out that the class consisting of "deep injuries without any superficial rent" is the one most often neglected and giving rise afterwards to displacements. In dealing with displacement of the uterus the many

In dealing with displacement of the uterus the many operative methods are considered, and the indication for each explained. The Alexander Adams operation is extensively illustrated, and the technique fully described, and many of the difficulties found in performing the operation explained, and the way to avoid them shown. Ventro-suspension after Howard Relf, or division of the round ligaments and suturing the ends into the abdominal wall, are the operations recommended when there is necessity for opening the abdomen. Ventro-fixation is advised only when the child-bearing period is passed, or after sterilisation. In closing the abdomen the author recommends No. 2 plain catgut for closing the fascia, and has found it satisfactory, but it appears rather insecure owing to the risk of too easy absorption. Curettage of the uterus and the indications for this operation are extensively dealt with at the end of the work. Some of the uses for the curette are open to criticism, and will not be universally agreed with, such as curettage for amenorrhæa due to mental disturbance, and in suspected cases of ectopic gestation before rupture for diagnostic purposes. Webster is quoted in support of this, but he points out that, although the finding of decidua is positive, the not finding is not negative. Also curettage should not be laid down as always necessary before plastic operations on the perinæum or uterus, for although the greater number of these patients have uterine disease as well as the other condition, there are a large number in which the endometrium is perfectly healthy, and therefore should be left untouched.

In spite of the inevitable points on which difference of opinion will be held, Dr. McKay has produced a book which will meet with general agreement in its essential parts, and which contains very few, and those very minor points for dispute. The illustrations are numerous and beautifully reproduced, and bring out the separate steps in the operations in a manner which makes them easy to follow and understand. The letterpress is large and clear, and the whole volume, which is crown 4to, with xxvii. and 454 pages, and 148 plates, is handsomely produced and well worth possessing by anyone who wishes to learn or who attempts to carry out the plastic operations on the perinæum and uterus.

### MEDICAL NEWS IN BRIEF.

#### Reyal College of Surgeons in Ireland,—General Meeting and Election of Officers.

A MEETING of the College will be held on Saturday, June 5th, at one o'clock, to receive the annual report of the Council.

A meeting will also be held on Monday, June 7th, at one o'clock, pursuant to the provisions of the

Charters, to elect a President, Vice-President, Council, and Secretary of the College for the ensuing year.

Fellows who may desire to have their names printed

Fellows who may desire to have their names printed on the list of candidates for office, will please signify their wish by letter, to the Registrar, at the College, on or before Tuesday, May 25th, as it is necessary to include the names in the voting papers which are forwarded to the Fellows; and no candidate is eligible unless his application is received within the date specified.

### St. Bartholomew's Hospital.

THE LORD MAYOR had a conference at the Mansion House on May 14th with the Masters and Clerks of the leading City Guilds with reference to the financial position of St. Bartholomew's Hospital. He read to them the following letter:—

Marlborough House,, Pall Mall, S.W., April 6th, 1909.

My dear Lord Mayor,

I am directed by the Prince of Wales to inform you that, as President of St. Bartholomew's Hospital, he has lately had an opportunity of learning from Lord Sandhurst, the treasurer, that there is now an annual deficit of about £12,000 in the working of the hospital, due in a large measure to payment of interest on a capital debt of approximately £170,000. His Royal Highness desires me to say that he has received this information with much regret, as he would view with grave concern the necessity for in any degree curtailing the work of what is the only general hospital within the City boundaries. His Royal Highness sincerely trusts that funds may be raised to prevent the possibility of such an unfortunate contingency.

Yours very truly,
ARTHUR BIGGE.

The Lord Mayor further stated that on a recent occasion the Prince of Wales had alluded, in conversation with him, to the same subject and emphasised his view that, as St. Bartholomew's was the only general hospital in the City of London, it behoved the citizens to see that its efficiency was fully maintained. Lord Sandhurst, the treasurer of St. Bartholomew's

Lord Sandhurst, the treasurer of St. Bartholomew's Hospital, who was present, gave details as to its financial position, explaining that some £170,000 was owing in respect of a loan contracted in 1902 in connection with the purchase of a portion of the site of Christ's Hospital and of other expenses in the development of the institution. There was now an excess of expenditure over income of about £12,000 a year. As showing the need of a hospital in the City, he mentioned that 620 beds were now occupied and that last week 385 cases of accidents were treated in the hospital. They at present got no help from King Edward's Hospital Fund, but they intended to apply at the next distribution.

The Master of the Mercers' Company handed in a donation of £500 towards the fund from his Guild.

### listrict Nursing Congress.

THE Jubilee Congress of District Nursing in Liverpool was held last week. Mr. Archibald Williamson, M.P., the Chairman of the Congress, who had been the host during their stay in Liverpool of Princess Louise and the Duke of Argyll, said Princess Louise had received a letter from the King in which his Majesty highly approved of her Royal Highness having come to the Congress, and he hoped it would result in very much good to the cause of district nursing.

wery much good to the cause of district nursing.

Sir Thomas Hughes presided at the first of two
sessions held in the morning, at which school nursing
in connection with district work was discussed.

Mr. H. R. Rathbone read a paper on "The Work of School Nursing in Liverpool." This, he said, was at first tried experimentally by the late Mr. William Rathbone in 1895, and about six or seven years ago it was taken over and extended by the committee of the District Nursing Association.

Sir Dyce Duckworth presided over another section, and Lady Helen Munro Ferguson introduced the subject of discussion—"The District Nurse." Directing attention to the standard required in the district nurse.

she said that at present no one was agreed either as to what constituted a trained nurse or what constituted a training. A definite standard for a fully trained nurse ought to be laid down by a nursing council, and then they would be able to make up their minds as to the

best kind of nurse to employ for district work.

At the concluding session several addresses were given on "Future Developments of District Nursing."

Miss E. F. Rathbone gave an account of an experiment which is being tried by the Liverpool Women's Industrial Union in establishing a new class of recruits as sick-room helpers. The Bishop of Liverpool presided and gave an address.

### Royal Sanitary Institute Dinner.

THE DUKE OF NORTHUMBERLAND, President of the Royal Sanitary Institute, was supported by a large assembly at the annual dinner of the Institute at the assembly at the annual dinner of the institute at the Langham Hotel, on May 11th, the company including Mr. Searles Wood (Chairman of the Council), Sir Francis Sharp Powell, M.P., Sir Dyce Duckworth, the Right Hon. Dr. R. Farquharson, Director-General Porter, R.N., Surgeon-General Sir Alfred Keogh, Sir Picture, Sir W. Emerger Sir Alfred Ready, and A. Binnie, Sir W. Emerson, Sir Henry Burdett, and

Sir J. Tweedy.
Sir A. Keogh, replying for the Services, pointed out that under the voluntary system of the Territorial Force the patriotism of the medical profession had given all that was wanted. It had been possible to give special work to men exclusively engaged in sanitation, a con-dition which was not fulfilled in any other army in Europe, and the service was now being completed throughout the whole force. He hoped by their efforts greatly to reduce the hospitals and humanitarian work, so that it would only be necessary to make provision for the wounded, and not for sufferers from disease which would be prevented.

The Duke of Northumberland, proposing the toast of the Institute, said that the advance of sanitation depended a good deal on the course adopted by the Government towards local authorities. On them had been laid new duties, but the people who did not recognise the necessities of the case resented the accompanying rise of rates. Much tact, therefore, was required in advocating reforms, and sanitarians should back local authorities in claiming assistance from the Exchequer to fulfil the new burdens laid on them by the Legislature.

### A Midwife's Character and an Alleged Palse Certificate.

AT the Eccles Police Court, on the 10th inst., charges were made by the Public Prosecutor under the Midwives Act against Mary Ann Marsh, Patricroft, who was accused of having procured admission to the midwives' roll by producing a false and fraudulent certificate of good character, and Dr. Sidley, who was accused of having aided and abetted the woman by signing the certificate. Mr. Ogden, acting for the

Medical Defence Union, appeared for the defendants. Inspector Howarth said that Mrs. Marsh, who applied in March, 1905, to be placed on the roll of midwives, had more than a dozen convictions against her for drunken and disorderly conduct, including two commitments since July, 1000, the last being in February of this year. When the present summons was served on Mrs. Marsh she was under the influence of drink, and she said she was sorry for Dr. Sidley, who had signed her certificate.

Evidence was given that Dr. Sidley had signed the certificate believing that Mrs. Marsh was a steady and very deserving woman, when he had no information to Evidence was not called to prove Dr the contrary.

Sidley's handwriting.

Mr. Ogden contended that Mrs. Marsh was sober, trustworthy, and of good moral character so far as her business life went, and that what she had done in her private life had no connection with her work as a midwife. With regard to Dr. Sidley, there was no evidence of wilfulness or fraud on his part. Whatever he had seen of Mrs. Marsh she had always been capable for her business.

The charge against Dr. Sidley was dismissed; Mrs. Marsh was sent for trial to quarter sessions.

#### The Hospital for Sick Chidren.

THE DUKE OF FIFE presided at the 57th Annual Court of Governors of the Hospital for Sick Children, Great Ormond Street, London, on Thursday last. The annual report referred to the opening of the new outpatient department, the cost of which was defrayed by Mr. W. W. Astor. The accounts showed an excess of income over expenditure of £714 16s. 2d., but on the other side there was a debt to the bankers of £4,500. With one exception, the income from every important source had increased during the past year. The mortage debt stood at five and the past year. gage debt stood at £15,349. The report was adopted on the motion of the Duke of Fife, seconded by Mr. Lucas. Lord Aberdare, moving the re-election of the President and Vice-Presidents, said he did not know how many institutions of the kind the Duke of Fife was connected with, but he was always faithful to that hospital. Mr. Arthur Lucas moved that sanction should be given to expenditure not exceeding £3,000 for the reconstruction of the old out-patients' department and explained that accommodation was to be provided for bacteriological research, an X-ray department, a dining-room, and other things. They were not launching out into any extravagance, he said, but the modern equipment of hospitals had become so complicated and extensive that they must carry it out thoroughly. The motion was agreed to, and sanction was also given to an expenditure of £563 on the reconstruction of a house for the accommodation of nurses who are sent out on private cases.

#### Royal College of Surgeons, England.

Royal College of Surgeons, England.

The following candidates, having passed the required examinations and conformed to the by-laws, were admitted members of the College on May 13th:—

A. Abrahams, B.A.Cantab.; H. W. L. Allott; Mukhtar Ahmed Ansari; R. R. Armstrong, B.A. Cantab.; J. L. Atkinson; K. J. Aveling; B. F. Bartlett; M. Bates, B.A., M.B.Oxon; Phirozshah Byramji Bharucha; H. E. Bloxsome; T. L. Bomford; W. F. Bowen; H. Bowrung, B.A.Cantab.; E. C. Braithwaite; T. F. Brown; W. H. Butler; F. G. Caley, B.A.Cantab.; F. G. Cawston, B.A.Cantab.; H. D. Clapham, A. J. Clark, B.A.Cantab.; J. P. Clarke; K. Comyn, B.A.Cantab.; R. B. Dawson; Canut Deuntzer; J. R. Dick, B.A.Cantab.; T. B. Dixon; J. R. B. Dobson; M. Donaldson, B.A.Cantab.; A. W. Duńcan; G. H. Dunn, M.A.Cantab.; L. W. Evans; T. Evans; P. C. Field; H. W. Gabe; E. B. Garrard; P. K. Gilroy, B.A.Cantab.; C. Gouldesbrough, M.A. Oxon.; H. S. Hall, B.A.Cantab.; D.J. Harries; T. Harrison; H. Hudson; E. P. L. Hughes; R. H. Hutchinson, B.A.Cantab.; V. P. Hutchinson; R. S. Ingersoll; R. P. Jones; C. F. V. Kebbell; Latafat Husain Khan; H. G. Kilner; S. J. Lee; R. H. Mawhood, B.A.Cantab.; J. K. Milligan; H. E. Hall Mitchell; E. B. Morley; H. R. Moxon; Naranji Ranchhodji Naik; F. C. Nichols, L.D.S.Eng.; R. D. O'Leary; D. G. S. R. Oxley; G. Smith; E. R. Stone, B.A.Cantab.; T. W. R. Strode; W. F. Sucliffe; H. L. Tasker; H. A. Treadgold, B.A.Cantab.; R. J. Vernon, B.A.Cantab.; D. Wainwright; H. C. Waldo; G. R. Ward; L. M. Webber; M. W. E. Wright, M.A.Oxon.

Conjoint Examinations in Ireland.

The following candidates have passed the final projection.

### Conjoint Examinations in Ireland.

Conjoint Examinations in Ireland.

The following candidates have passed the final professional examination of the Royal College of Physicians and the Royal College of Surgeons, May, 1909:—B. G. S. Boles, F. H. Gleeson, H. G. Massey-Miles, R. Power, E. Smith, G. C. Sneyd, C. H. Stringer, B. Wallace, J. McG. Williams.

Diploma in Public Health:—Capt. W. W. Browne, M.R.C.S., L.R.C.P., R.A.M.C. (with honours), R. F. O. Dickinson, L.R.C.P. and S.I., R.A.M.C., B. D. Gibson, L.R.C.P. and S.I., D. J. O'Connor, M.D. R.U.I., F.R.C.P.I., Capt. N. D. Walker, M.B. Univ. Edin., R.A.M.C.

### Summary of Recent Medical Literature, English and Foreign.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

The Treatment of a Case of Extensive Infantile Paralysis by Operation and Apparatus.—Rowlands (Brit. Med. Journ., April 10th, 1909) describes the case of a girl, æt. 17, whose hips and knees on both sides were fiexed and the lumbar spine arched, the result of infantile paralysis when three years old. Standing and walking were impossible, but the patient could shuffle along by grasping and moving her feet with her hands. along by grasping and moving her feet with the maintained. The paralysis appeared to be complete below the waist except for the power of—(1) very weak extension and abduction of the right hip; (2) weak flexion and adduction, and very weak abduction and extension of the left hip; (3) slight power in the right peroneus tertius and the flexors of the toes, and of the left calf muscles. Both ankles were flail. The reflexes were abolished in both legs, but sensation was unimpaired. The following operations were carried out at one sitted. ting: While the left index finger was kept constantly over the anterior crural nerve, a curved long tenotome was introduced about 1 in. below and outside the anterior superior spine between the skin and the auterior contracted structures, which were gradually divided, while an assistant pressed the knee backwards. Through the same puncture wound the shortened fasciæ on the outer side and the abductors were divided. spite of vigorous manipulations, it was not possible to straighten the hip till the anterior tissues were divided down to the neck of the femur. The shortened tendons behind the right knee were next divided subcutaneously, the left knee not requiring this. The kneejoints were opened through curved incisions across the patella ligaments, which were divided, and the upper end of the tibia and the lower end of the femur, just short of the epiphyseal line, were sawn off in each limb. Thus each limb had to be shortened about an inch and a-half before it could be straightened without exerting too much tension upon the contracted popliteal vessels and nerves. The knee-cap and a good deal of pendulous skin was removed on both sides. The patient was at once fixed in a double Bryant's splint without extension. Five weeks after operation an apparatus was applied, and the patient was instructed and helped to learn the arts of balancing, standing, and walking. The apparatus was provided with toelifting springs and T. valgus straps. There were no
joints at the knees, which were kept firmly fixed by The side-irons were made to take some of the weight off the legs, and the whole apparatus, including the pelvic girdle, added to the stability of the body. When the patient left hospital nine weeks after operation she could walk on the level with the aid of a little support from crutches, and could stand alone without these.

Transfusion of Blood for Pernicious Anæmia.—Lucy (Med. Rec., March 6th, 1909) reports a case of a woman, æt. 33. who, 18 months after he had operated on her for kidney abscess, developed pernicious anæmia during pregnancy. A living eight months' child was born on August 5th, 1908, with no loss of blood or sepsis. The anæmia and distress grew rapidly worse. The blood count showed 1,800,000 red blood corpuscles; hæmoglobin, 35 per cent.; megaloblasts present. Repeated blood examinations showed a condition of pernicious anæmia. On August 13th the author connected the husband's right radial artery with the patient's median basilic vein, and the blood was allowed to flow for 70 minutes. On August 14th her condition was better, and on the 15th she developed an appetite and ate a good breakfast. Colour returned to the nails and underneath the tongue, and from this time on improvement was very rapid, and she was discharged in good health on September 15th. A blood count on October 4th showed red blood cells 3,200,000,

with hæmoglobin 85 per cent.; no megaloblasts. According to later reports the patient's health is perfect. S.

Fistula Between the Stomach and Bile Passages, and Other Internal Biliary Fistulæ.—Mayo Robson (Brit. Med. Journ., 1st May, 1909) points out that though this condition may result from the breaking down of malignant growth, from ulceration of the stomach, duodenum, or colon, yet the most frequent cause of internal biliary fistula is gall-stones. The fistula may be either direct, or indirect through an abscess cavity. Usually the ulceration leading to fistula proceeds quietly and painlessly, producing very few symptoms, until, it may be, a gall-stone sets up absorption in its passage down the intestinal canal; or, after the formation of a fistula, all the symptoms pass away, and the patient makes a complete recovery. The author reports a case in which symptoms occurred due to gall-stones passing into the cystic and common ducts, the fistula having contracted. Sometimes pain beneath the right costal margin, more or less continuous fever of an irregular type possibly associated with rigors, are symptoms which accompany the formation of fistula. On examination there will be found rigidity of the right rectus, distension of the upper abdomen, and possibly a tumour. There may also be hæmorrhage, vomiting of gall-stones, and symptoms of intestinal obstruction. Intestinal obstruction may be acute, caused by local peritonitis leading to paralysis of the bowel; by volvulus of the small intestine; or there may be mechanical obstruction due to the passage of a large concretion through the small intestine. The writer cites a case in which a minute fistula into the colon was overlooked when separating very dense visceral adhesions, the result being the escape of visceral contents and peritonitis. Cases are also mentioned which leads the author to consider that silk ligatures at any operation on the biliary passages is fraught with risk of subsequent trouble.

Direct Blood Transfusion .- Berg (Med. Record, March 27th, 1909) records several cases in which this operation was performed with satisfactory results. He advises that no blood transfusion should be attempted except in cases of urgent necessity without previously determining whether the donor's blood will hæmolyse the blood of the recipient. With improved technique the modern operation is unattended with risk to the donor or the recipient. The basic principle of the anastomosis is to bring the intima of the artery everywhere into contact with the intima of the vein. The vessels to be anastomosed are first exposed and freed from their surroundings for about an inch, and clamped proximally and distally. The artery and vein are then divided, or an incision is made into the side of the vein if a lateral anastomosis is to be effected. After passing two guide sutures to hold the vessels lightly in contact, a fine, twisted, silk, continuous, through-and-through suture is used to complete the anastomosis. The method of anastomosis described by Crile, in which cannulæ are used, is an excellent and speedy procedure. There is as yet no means of measuring the amount of blood that is transfused. It has been the custom to depend upon the increase of hæmoglobin percentage of the recipient as a rough indication of the amount of blood transfused. percentage is taken before and every ten minutes during the operation. From a normal adult man sufficient blood can usually be transfused to raise the hæmoglobin of an adult donee to 65 or 70 per cent. The donor's blood during the transfusion does not show a proportional decrease Besides its use in severe acute hæmorrhage, the writer has found blood

transfusion to be one of the best means of preparing feeble and exsanguinated patients for major opera-tions. The author reports several cases which he has successfully treated.

Anæsthesia.-Humphry (Practitioner, Chloroform May, 1909) discusses the advantages of using chloroform as an anæsthetic in those instances in which the patient's general condition is manifestly very bad, and in which it is imperative that a general anæsthetic should be administered, and some inevitable operation performed. Such cases are not unusual when the patient is the subject of cancerous disease or suffering from septic infection. In such patients the heart is often failing, and this has been looked on as a special indication for the administration of ether rather than chloroform. Humphry is of opinion that if ether is given in such a case the tired heart is injuriously stimulated, and is scarcely able to respond, and, by raising the blood pressure, the amount of work it has to perform is increased. If, on the other hand, chloroform be given, the feeble heart is not stimulated, but the amount of work it has to perform is diminished by lowering the general blood pressure. In support of these views, Humphry quotes the Lancet and Hyderabad Commission's report on chloroform as follows:—"Chloroform has no power of increasing the tendency either to shock or syncope during opera-tions," and "if either shock or syncope from any cause does occur, it prevents, rather than aggravates, the dangers of chloroform inhalation; that in fatty degeneration of the heart chloroform in no way endangers it, but, on the other hand, is a positive advantage, by virtue of lowering the blood pressure and lessening the work it has to perform.'

The Pre-Systolic Murmur.—Gill (Australasian Med. Gaz., March, 1909) criticises the ordinary view of the actual causation of this murmur that it is caused by the vibration of the roughened mitral valve as the blood passes over it from the left auricle into the ventricle. He has recently investigated a case where the presence of a rough diastolic murmur and thrill at the apex led to the diagnosis of mitral stenosis, but at the autopsy no mitral stenosis, but great hypertrophy of all parts of the heart, was found. He also refers to the 46 cases collected by Dr. Phear, in which a presystolic apex murmur was present, but no mitral stenosis. The explanation which Gill offers of the causation of this murmur is as follows:-"The presystolic murmur is chiefly an auricular sound, or rather series of sounds; the murmur is usually compounded of two sounds, muscular and valvular-the first of which is the more important, while the second is not essential." He believes that in cases of mitral stenosis with a pre-systolic murmur the contraction of the auricle is not single, but multiple: "That a series of short contractions occur one after the other, culminating in one powerful contraction which occurs immediately before the contraction of the ventricle; that each contraction produces a sound which is conducted by the ventricular muscle to the apex." The valvular component of the pre-systolic murmur is represented by the mid-diastolic murmur of mitral stenosis. In confirmation of these views tracings are shown from the jugular and epigastric pulsations of a man, æt. 53, with old-standing mitral stenosis. "All the tracings have the same characters—viz., that the ventricular diastole is entirely occupied by a series of small waves, which even continue during the systole of the ventricles. These waves in the jugular can only be due to the contraction of the right auricle." K.

Therapeutic Value of Radium .- MacLeod (Practitioner, May, 1909), in discussing the therapeutic value of radium, speaks of the results he has obtained from its use in lupus vulgaris. On the whole, these results have been disappointing. It was found possible 10 cause the apparent disappearance of the nodules of lupus by the use of radium, but in nearly every case recurrence supervened. This was especially marked in those cases where the disease involved the mucous membrane of the nose and mouth. In these cases relapse. after temporary improvement, occurred.

The Treatment of Tinea Tonsurans.—Sutton (Amer. Journ. Med. Sciences, March, 1909) relates certain investigations which he has carried on with regard to the treatment of ringworm of the scalp. With some difficulty a white rabbit was infected with a small-spored ringworm obtained from the hair of a four-year-old patient. One of the two patches resulting from this infection was subjected to an eleven-minute exposure from a Piffard model cancer tube at a low vacuum, the window being placed 6 cm. from the area. Ten days later, there being no perceptible reaction, a second exposure of 12 minutes was given. Fifteen days later the hairs became loosened, and denudation was complete at the end of a week. One-half of the bald area was then thoroughly covered with the follewing mixture: Iodine crystals, 1.75; potassium iodide, 1.25; goose grease, 25. Some time later a portion of each half was excised and submitted to histological examination. Practically no inflammatory changes were found, but the iodine mixture was seen to have penetrated to the bottoms of practically all the follicles in the treated area, and to a considerable depth in the appended glands. Quite a number of fungi remained in the cavities, along with small portions of broken hair cuticle. The other patch, which tions of broken hair cuticle. The other patch, which had not been submitted to the X-rays, was treated with the iodin-goose grease mixture, heat and friction being employed. Half-an-hour later a 2 per cent. solution of mercuric chloride in goose grease was applied. This application was repeated twice, at intervals of a week, and a fortnight later the patch showed decided signs of improvement. Similar experiments were carried out on other rabbits, with the result that the area treated by the drugs alone appeared to improve quite as fast and quite as satisfactorily as the area depilated by the X-rays. Similar good results were obtained in the cases of five children, where the microsporon was the infecting fungus in each case. Dr. Sutton believes that goose grease is superior to other fats as a skin penetrant. The powerful effect of the iodine, followed by the mercuric chloride, is due, not to the individual action of either agent alone, but to a third, mercury iodide, an extremely active and powerful, but relatively unstable, salt, which is formed at the points of contact.

Treatment of Tuberculosis .- Stern (Cleveland Med. Journ., March, 1909) gives his clinical experience of the use of Koch's tuberculin for the treatment of tuberculosis of bones and joints during 18 months. The method of using the tuberculin which he has adopted is that advocated by Trudeau. In this method one begins with minute doses, 1/10,000 or 1/1,000 of a milligram of Koch's tuberculin, and gradually increases it till the dose has reached 1/100 of a milli-gram. This dose is continued for some weeks, and then the treatment is begun over again. As a guide for the size of the dose, the interval between the doses and the increase in the amount of the dosage, every discoverable objective and subjective symptom of the disease is made use of. The method is purely clinical, and the object is to avoid altogether all reactions of any kind. Dr. Stern lays great stress on the importance and value of thus being able safely to use the tuberculin treatment under the guide of clinical symptoms, since regulation by the investigation of the opsonic index is too costly to permit of its use in general practice. While using the tuberculin it is important not to neglect any of those other methods of anti-tuberculous regime, such as fresh air, good food, and physical and physiological rest. When used in this way Dr. Stern has found the treatment an invaluable aid. His cases have done better than they would have done without its use. They have responded quicker, and have been discharged in less average time than ever before. Complications have either been avoided, or, when present, have subsided on its continued exhibition. This has been especially noticeable in his adult or older cases, in some of whom the gain in weight and strength has been truly remarkable.

### NOTICES TO CORRESPONDENTS, &c.

Correspondence requiring a reply in this column are particularly requested to make use of a Distinctive Signature or Initial, and to avoid the practice of signing themselves "Beader," "Subscriber," old Subscriber," etc. Much ognfusion will be spared by attention to this rule.

### SUBSCRIPTIONS.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January lat and July lat respectively. Terms per annum, 21s.; post free at home or abroad. For India, Foreign subscriptions must be paid in advance. For India, Foreign subscriptions must be paid in advance. For India, Foreign subscriptions are Rs. 15.12. Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

necessarily for publication but as evidence of mentity.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

should be addressed to the Publisher.

M.D. (Staines).—Caravans can be obtained of several London firms—either with or without the necessary horse or horses. For healthy and vigorous persons the outdoor wandering life forms a complete and wholesome contrast from ordinary domestic forms a complete and wholesome contrast from ordinary domestic one must be prepared for a certain amount of exposure. In wet weather tempers are apt to be strained, and there is little shelter to be had except within the van. It is well to have advice from experienced travellers as to the best routes to follow. The holiday passed on wheels is apt to be costly, but it is a pleasant change for folks of the outdoor temperament.

MEDICAL MEN AND THE TAX ON PETROL.

International metrical Congress, together with the notes and lodging arrangements at Buda-Pesth in our issue for April 28th.

MEDICAL MEN AND THE TAX ON PETROL.

MR. LLOYO GEORGE has again refused to grant a rebate on the petrol used in motor cars by medical men, but he has offered to receive any deputation, which is representative, on the subject receive any deputation, which is representative, on the subject will wait on Mr. Lloyd George with the object of learning, amongst other points, in the words of Mr. Chlozas Money, "on what principle a special incom: tax has been imposed on doctors who use motor oars in the course of their professional work."

J. W. B.—We have searched the official Medical Register, and also the Medical Directory for 1909, and cannot find the name. You may assume, therefore, that he is "unqualified," or has been struck off the Register.

DR. Hr. G. is thanked for his communication. The suggestion in the second part of his letter has been acted upon.

S. M. (Manchester).—It looks suspicious, but it would be right to swait developments.

## Meetings of the Societies, Tectures, &c:

Wednesday, May 19th.

Medical. Graduates College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. Mr. Collier: Clinique (Surgical).
5.15 p.m.: Lecture: Sir Thomas Oliver (Newcastle): Some Unusual Features of Lead Poisoning.

GRUNTLETT, E. G., M.R.C.S., L.R.C.P.Lond., Senior House Physician at King's College Hospital.

Gleson, H. E., M.B., B.Ch.Oxon., House Surgeon at King's College Hospital.

siclan at King's College Hospital.

GIBBON, H. E., M.B., B.Ch.Oxon., House Surgeon at King's College Hospital.

GIBBON, H. E., M.B. Lond., F.R.C.S.Eng., Junior Resident Resident Medical Officer at Queen Charlotte's Hospital.

HUGHES, BASH., M.B., B.C.Cantab., M.B.C.S., L.R.C.P.Lond., Junior House Physician at King's College Hospital.

MCCALL, J., L.R.C.P.Edin., House Surgeon and Secretary to the Hertford County Hospital.

MCDONALD, C. E. W., M.R.C.S., L.R.C.P.Lond., House Accoucheur at King's College Hospital.

PORTER, CHARLES, M.D., C.M.Edin., M.R.C.P.Edin., Medical Officer of Health of Marylebone.

PRESCOTT, N., M.R.C.S., L.R.C.P.Lond., House Surgeon at King's College Hospital.

### Pacancies.

St. George's Union, London.—Second Assistant Medical Officer.
Salary, £120 per annum, with board, residence, and washing. Applications to the Medical Superintendent.

£150 per annum, with board, lodging, and washing. Applications to the Medical Superintendent, Caterham Asylum.—Third Assistant Medical Officer. Salary. £150 per annum, surrey.

National Hospital for the Paralysed and Epileptic, Queen Squar, Bloomsbury, London, W.C.—Senior Dispenser. Salary, £150 per annum. Applications to Godfrey H. Hamilton, Secretary, king Edward VII. Sanatorium, Midhurst, Suasex.—Senior Assistant Medical Officer. Salary, £150 per annum, with board, lodging, and attendance. Applications to the Hon. Secretary, 19 Devonshire Street, Portland Place, London, W. The Earlswood Asylum, Redhill.—Junior Assistant Medical Officer. Salary, £130 per annum, with board, lodging, and washing. Applications to the Secretary, 36 King William Street, London Bridge, E.C.

Berks County Asylum, Wallingford.—Second Assistant Medical Officer. Salary, £140 per annum, with board, furnished apriments, attendance, etc. Applications to the Medical Superintendent.

London County Asylum, Colney Hatch, New Southgate, N.—

Superintendent.

London County Asylum, Colney Hatch, New Southgat, XJunior Assistant Medical Officer. Salary, £160 a year, with
board, furnished apartments, and washing. Applications:
H. F. Keene, Clerk of the Asylums Committee, Asylum
Committee Office, 6 Waterloo Place, London, S.W.

Reckett Hospital, Barnsley.—Surgeon. Salary, £150 per annun
with board and lodging. Applications to R. F. Parsey, HoSecretary, 8 Regent Street, Barnsley.

Suffolk District Asylum, Melton.—Second Assistant Medica
Officer. Salary, £160 per annum, with board, turnish:
apartments, attendance, and laundry. Applications to the
Medical Superintendent.

### Births.

MAILEE,—On May 12th, at Rookdene, Alexandra Park Road, Musve Hill, the wife of William Maller, M.B., C.M., of a son. MITOHBLL—On May 13th, at Eastgate House, Guildford, the wife i Arthur M. Mitchell, M.D., Cantab, of a son.

### Marriages.

MEILO—HAWKINS.—On May 11th, at St. Lawrence Church, inster, Peter Paul Elliott Mello, son of Mr. and Mrs. Mr. of "Rosebank." Sidley, Bexhill, to Margaret Emily. & daughter of F. M. Hawkins, M.D., of "Chapmans," Upming

### Beaths.

BOULTON.—On May 15th, at Seymour Street, Portman Squinon, in his 68th year, Percy Boulton, M.D.Edin., M.B. London, after a long and serious illness. London, after a long and serious illness. Don May 15th, of pneumonis, William Ferris, M.D., Assimedical Officer, Middlessex County Asylum, Wandsworth Corlection, uged 34.

WHITTLE.—On May 2nd, at Las Palmas (Canarics), Edward Growth Wilson, On May 15th, at Dean's Grove, Guildford, Lieurer Colonel James Wilson, R.A.M.C., son of the late Thomas Wilson, aged 73.

# Peptogenic Milk Powder

- Cows' milk prepared with PEPTOGENIC MILK POWDER becomes remarkably like mothers' milk in all particulars: in physical properties, in colour and taste, and in the percentage of nutritive constituents: in its digestibility, its behaviour with acid, with rennet, and in the infant's stomach.
- Milk prepared with the PEPTOGENIC POWDER has simply the normal digestibility of mothers' milk: is not too easily or unnaturally digestible, and contains no aid to digestion. It affords a complete substitute for mothers' milk during the entire nursing period.

Supplied to the Medical Profession in two sizes, at 1/10 and 3/8 each.

# 'Pepsencia'

PEPSENCIA is an ever-ready digestive fluid possessing remarkable peptic and rennet activity. It contains pure pepsin, the vitality of which is unimpaired by chemical action or manipulation, and it is obtained by direct solution from the secreting glands of the gastric mucous membrane, every care being exercised to preserve its full physiological activity.

The usual dose is a teaspoonful before or after meals in all cases where pepsin is indicated. Supplied to the Medical Profession in 4 oz. and 8 oz. bottles, at 1/10 and 3/3 each.

# 'Panopepton'

PANOPEPTON presents the entire substance of prime lean beef and best wheat flour in a perfectly soluble, diffusible, and absorbable form. It is at once a grateful stimulant and food.

For an adult, the usual portion should be a dessertspoonful to a tablespoonful several times a day and at bedtime.

Supplied to the Medical Profession in 6 oz. and 12 oz. bottles, at 2/2 and 3/8 each.

Specimens and literature will be forwarded on request.

Originated and Manufactured by

Fairchild Bros. & Foster, NEW YORK. Agents for Europe, Asia, Africa, and Australasia:

Burroughs Wellcome & Co., LONDON. SYDNEY. CAPE TOWN

# Mellin's Food

Mellin's Food is adapted for the use of children of all ages,

for the following reasons-

- Chemical and microscopic tests prove MELLIN'S FOOD to be absolutely FREE from starch.
- MELLIN'S may be used in varying quantities to adjust the proportion of Carbon and Nitrogen.
- MELLIN'S aids the emulsification of fats.
- 4. Assists digestion without usurping the functions of the digestive secretions.
- Supplies valuable organic compounds of Phosphorus and Potassium.
- 6. May be used in any variable proportion which the demands of the child or the experience of the physician may dictate.

MELLIN'S FOOD has received the highest awards at the International Exhibitions held during the past 40 years.

Samples of MELLIN'S FOOD, with tables of analyses, sent FREE to Members of the Medical Profession.

MELLIN'S FOOD, Ltd., Peckham, London, S.E.

### Notes and Comments.

The Burial of the Still-born.

WE have received some interesting communications regarding our "Leader" of May 12th on the Cornish burial scandal. The fact that in the year 1909 both the manager and the

gravedigger of a public cemetery are in the habit of burying as "still-born" infants who have survived birth from a few days to several weeks shows the necessity of supervision as well as of legislation in such matters. Abuses in connection with still-birth burials have been recognised ever since the registration of deaths became compulsory and general. So long ago as 1866—a correspondent points out—Mr. F. W. Lowndes exposed these abuses, first in Birmingham and afterwards in Liverpool. His writings attracted the notice of the Home Office, and it may be safely assumed that they formed the basis of the Burial Acts Amendment Act of 1874. It is somewhat startling to find the salutary provisions of that measure regarding the burial of the still-born absolutely a dead letter in the year 1909, and it is to be hoped that the Home Office will take steps to prevent the recurrence of scandals such as those exposed by the recent inquest at Ludgvan. The disclosures made upon that occasion are of a most serious nature, and in our opinion suggest the desirability of a general inquiry into the conduct of cemeteries with regard to this and other administrative matters.

and Still-births.

It is no less disquieting to find that The Midwife a midwife who has been raised to the dignity of a State recognition should know nothing as to her duties and responsibilities under the Burial

Acts. At the Cornish inquest the certificated midwife concerned admitted that she had never read the regulations with regard to still-births. Failing the presence of a registered practitioner at the birth, a midwife is entitled to grant a certificate that the child was still-born, upon which the body may be buried. So serious a view is taken by the law of any abuse of the power, that a false declaration involves a penalty of £10, or an alternative of no less than seven years' penal servitude. With this possibility in view, it is curious that persons should be found ready to run so much risk for reasons that must necessarily be inadequate. Good nature and the desire not to offend clients or neighbours by adding to their perplexities are easily-understood motives, but at the same time they are apt to lead their owners into a deadly pitfall. It is to be hoped that the Central Midwives Board will firmly grasp the moral of the Ludgvan case, and ascertain once and for all that midwives are acquainted with their duties and responsibilities under the Burial Acts before they receive their certificate of fitness to practice midwifery.

A Human Reptile.

THE frequency of the crime of procuring abortion must be much greater than is commonly supposed. Not only by the nature of the crime must an enormous number of opera-

tors, male and female, escape detection, but when from time to time one of them is laid by the heels, the police are generally able to show that the criminal has enjoyed a long period of immunity, owing to their inability to get evidence sufficient to justify a prosecution. One of these vile creatures was tried at the Old Bailey last week, owing to the death of one of her unfortunate victims from septic peritonitis. The charge of murder was put forward, but the jury, for some reason which certainly does not appear, reduced the crime, as they had power to do, to manslaughter, and of this they found her guilty. The prisoner, although only thirty-nine years of age, had been watched by the police in connection with abortion for no less than twelve years, and they had received numerous complaints about her. Her husband, now dead, who is said to have been a doctor, but was probably a low type of charlatan, was convicted of performing an illegal operation in 1898, and sentenced to seven years' penal servitude. Her servants had on three occasions found parts of children's bodies in the grate, and they gave evidence of many women having stayed in the house at one time and another.

The Home Office and

MR. JUSTICE DARLING, in passing sentence, said what was true when he remarked that the jury had taken Abortion. a merciful view of the prisoner's crime in not finding her guilty of murder, and we have no doubt that had she been

a man they would have convicted her of the major crime. In the judge's opinion, people like the prisoner deserve the death penalty, and we thoroughly agree with him. A woman who systematically carries on the vile practice of abortionmongering year in and year out deserves not the slightest particle of pity or leniency. Single occurrences under special conditions may deserve to be treated differently, but regular and oft-repeated crime should put the perpetrator beyond the pale of mercy. Mr. Justice Darling sentenced the prisoner in this case to ten years' penal servitude, and made the curious remark that "he would have passed a longer sentence upon her but for the fact that it might be reduced by the Home Office to the kind of stereotyped sentence which they allowed." Are we to understand from this that the Home Office have fixed rules for over-riding long sentences?

We have over and over again pointed out the stupidity of long sentences in many classes of crime, but we can hardly imagine that in the case of a notorious and inherently wicked prisoner of this type they would reduce any sentence, however long, which a judge imposed on her.

WE have not much experience of

"Do Doctors our contemporary the Christian Disease Commonwealth, but our attention Children ?" has been drawn to an article in last week's number bearing the ungrammatical headline, "Do Doctors Disease Children?" We are tempted to follow that journal in its distortion of the English language by asking if it thinks it "Christians" its readers by making itself party to any such atrocious suggestions? Happily the reply to the query is dealt with by a Miss Margaret McMillan, who, though she professes herself an anti-vaccinationist, writes with uncommonly good sense on the subject. She says :- "If this is true, the medical profession is a fiendish one. and fiendish persons alone would uphold it. Is it not time for all of us anti-vaccinators to put away such fearful suspicions, and to admit that, though wicked men may get into this profession, or into any other, yet the profession itself is not a fiendish one? It numbers in its ranks many quiet heroes. The average member of it is utterly incapable of the crimes sometimes laid to his charge." She goes on pertinently to point out that diseases come from dirt, ignorance, and unhealthy conditions of life, which doctors are doing their best to combat, and that vaccination is an unpleasant alternative to hygienic measures which people will not take for themselves. We may truthfully say of Miss McMillan that she is the first anti-vaccinator we have met with who seems to have studied her subject, to be tolerant and broad-minded, and to be animated by that charity that speaketh not evil.

Honone.

A SAD case was inquired into by the A Prophet, Halifax Coroner last week, in which not Without a Sowerby woman who during her last illness had no other attendance than that given by a local herbalist,

was found at the post-mortem to have died of peritonitis. The coroner said he did not purpose to call any further evidence, but the jury objected, saying they thought "Dr." Culpan, the herbalist in question, should be given an opportunity of giving evidence. The coroner said he did not think it worth while, as the case was obviously one of death from natural causes. The foreman then took up the cudgels and asked if a post-mortem was necessary, for the people of Sowerby had known "Dr." Culpan for thirty or forty years and had great confidence in him. "They felt," he said, "that of late years the coroner had taken the idea that he was a mere quack-a man who was going and coming. He had, on the contrary, grown up amongst them and was a very respectable man." This is certainly a new definition of a quack-a man who comes and goes-and for our part we should hardly feel justified in entrusting our lives to a man merely because he had grown up amongst us; but, as the coroner pointed out, the real question was whether the woman's life could have been saved by proper medical treatment.

### LEADING ARTICLES.

THE MEDICAL DEFENCE UNION.

For nearly a quarter of a century the duty of collective medical defence has been conducted by an effective professional body. During that period the work that has been accomplished has more than justified the energy of the self-sacrificing labour that has created and maintained that most necessary organisation. The first of these bodies-there are now three of them in active work-was the Medical Defence Union, and we turn with pleasure to their recently-issued Annual Report and Statement of Accounts for the year 1908. It is encouraging to find that the average increase has been maintained by the accession of 478 new members during the year under report, while the number on the register reaches the considerable total of 7,761. The financial condition of the Union is satisfactory, and they have at their back the sum of some £10,500 in the shape of a guarantee fund to fall back upon in any great emergency. The assets at the end of the year amounted to some £4,000, which should form the nucleus of a solid reserve fund as the years go by. The greater part of the expenditure has been due to legal costs, namely, £2,081 28. 11d. The Union would benefit greatly were our costly and cumbrous system of legal procedure simplified and were cheap law conferred upon British citizens. One of the features of the year has been the conclusion of an arrangement with the Yorkshire Insurance Company, whereby any member of the Union may take out an indemnity insurance covering his law costs in any action in which he may be concerned as defendant for negligence qua practitioner. The practical value of the Union to members is well expressed by the President, Dr. Stamford Felce, as follows:-"The (legal) cases are varied, but each would, if left to the individual practitioner to deal with, have cost him considerable anxiety, expense and trouble, which have been saved him by reason of his membership. Numerous letters of cordial thanks and gratitude for services rendered have been received from members during the year. These letters have served to show that the value of the legal assistance afforded has been greatly appreciated by those who have sought it, and have more than ever proved the necessity for the existence of the Union. It is difficult to imagine what would have happened if the practitioners concerned had not been able to secure such aid, advice and timely help; it can be said with absolute certainty that many of them would have been greatly harassed and seriously embarrassed." The Union is fortunate in the possession of two officials with an unrivalled experience of medico-legal questions in the persons of the secretary, Dr. A. G. Bateman, and the solicitor, Mr. W. G. Hempson. From the report of the latter we learn that 128 cases were actually carried through and completed, in addition to the very large number of instances in which advice was given, the matter settled out of court or otherwise disposed of. Of the 128 cases, 45 were within the metropolitan area, 70 in the provinces, 4 in Scotland, 2 in Ireland, and 7 in Wales. Of the completed cases, 40 were for libel and slander taken or defended on behalf of members; 25 were to defend

actions brought against members for malpraxis. It is interesting to find that accusations under the last-mentioned heading are frequently heard of for the first time when the plaintiff has been proceeded against in the County Court for recovery of medical fees. In one particular instance a patient brought a charge of negligence against his medical attendant who had failed to diagnose a condition discovered by operation. The case was decided against the plaintiff who, in spite of his apparently good financial position, was unable to pay the taxed costs of the action, amounting to £300. The Council of the Union regarded extreme measures as justifiable and instituted bankruptcy proceedings, but as the debtor's assets were returned as under £20, the whole costs, amounting to £350, fell upon the Union. This experience emphasises a grave defect in British law, where a man of straw is enabled to bring an action-it may be even vexatious and frivolous to a degree—but the unfortunate defendant has to pay enormous costs in spite of his having won the suit. The moral, however, so far as medical men are concerned, is that by the simple payment of ten shillings a year the member in the case referred to was saved a heavy pecuniary loss, besides having his action conducted in a skilled legal manner. The annual report of the Union affords some interesting reading, and practitioners will hardly fail to gather various suggestive hints of practical value from its perusal. In conclusion, we strongly urge all medical men who are not already members of the Medical Defence Union, or of one of the companion societies, to lose no time in joining an organisation of such conspicuous value and comfortable prudence.

### CURRENT TOPICS.

### Workhouse Babies.

We recently had occasion to refer to the criticism passed by the Local Government Board on the figures and conclusions with regard to infantile mortality in workhouses set out in the Minority Report of the Royal Commission on the Poor-laws. A good many individual protests of a similar type seem to be forthcoming, and the impression made on us is that the zeal of the minority seems to have carried them further than the actual ascertainable facts justified. But we are glad to see that the matter is arousing real interest and that guardians are actually bestirring themselves to find out how far their own institutions are at fault. This is a healthy sign, and we hope each board throughout the country will do the same. A special report by Dr. Dodson has been presented to the Wandsworth Guardians on the infantile mortality in the Wandsworth Workhouse, in which it is shown that the mortality in the first week of life for infants bern there is 24 per 1,000, which is little more than half of the average 42 per 1,000, as given by Mrs. Sidney Webb in a letter to the Times. Many of these deaths Dr. Dodson attributes to pre-natal and maternal conditions, and as the mothers have been poorly nourished, have often been dosed with noxious drugs, and have suffered terribly from mental worry, he does not regard this fact as surprising, and indeed it is not. Taking these considerations into account, he thinks there is nothing to be ashamed of in a death-rate of 24 per 1,000 in the first week of life. Mrs. Webb had pointed out that proper quarantine accommodation should be provided for newcomers, but Dr. Dodson says that with forty or fifty young children arriving a week the proposition is obviously impossible and verges on the ridiculous. On that point we are not sure that we agree, as the question is one which could be solved if sufficient accommodation of the kind were provided by the guardians, though to do so would be a matter of no small expense. It is more doubtful if the expense and trouble would give adequate results, for the problem of quarantine is a most complicated one if it is to be dealt with thoroughly and logically. At any rate, Dr. Dodson seems to be justified in his conclusion that workhouse mothers and children are better fed, better clothed, and better cared for in every way than among the poorer classes outside, and the guardians were satisfied with the report.

### Preserved Sausage.

THE interesting question, When is a sausage not a sausage? was before the justices at the Newington Sessions last week in an appeal by G. F. Hayward, pork-butcher, of Mayfair, against a conviction by Mr. Mead, sitting at Marlborough Street Police Court, imposing a fine of 40s., and £5 5s. costs, for selling a certain article of food-to wit, pork sausage-not of the nature, substance and quality of the article of food demanded by the purchaser. A Westminster sanitary inspector had bought some sausages from Hayward which proved on analysis to contain 22.4 grains of boracic acid to the pound, and Mr. Cribb, public analyst for Westminster, and Dr. F. J. Allan, medical officer of health for the same city, gave evidence that boracic acid was unnecessary and injurious, that its presence could not be detected by the consumer, and that its danger lay in concealing and arresting decomposition which was just about to begin. Mr. Cribb admitted in cross-examination, however, that ten or twelve years ago the majority of sausages contained boracic acid. For the appellant, counsel submitted that boracic acid was a necessary ingredient in the preparation of sausages, that some preservative, such as salt or saltpetre, was always used, and that the purchaser was in serious danger if no preservative was used. Dr. Klein gave evidence, saying that he had undertaken experiments for the National Federation of Meat Trades' Association, and that he had actually recommended them to use 26 grains of boracic acid per pound, as otherwise the sausages would not keep good for twenty-four hours. Another witness went so far as to say that a commercial sausage without boracic acid is not a sausage, and that the proper proportion is 35 grains to the pound. In the end, the chairman decided to reserve his judgment and to state a case for the High Court if desired. Now this matter is one of great public importance, for sausages are a favourite food of all classes, they are peculiarly liable to have all sorts of material used in their manufacture, and the amount of illness traceable to sausages is by no means small. It must be a great temptation to a butcher whose meat will no longer keep fresh to mince it for sausages and put in a little boracic acid as a preservative, though it is hardly credible that fresh meat made into sausages

will not keep for twenty-four hours. In face of the decision against putting boracic acid and other preservatives into milk, butter and cream, it is hardly possible to see how the appeal can succeed.

The Forthcoming Tuberculosis Exhibition.

A VALUABLE object-lesson is being prepared by the National Association for the Prevention of Consumption in the shape of a Tuberculosis Exhibition. The meeting will be held appropriately in the East End of London, for it is there that the disease claims its greatest toll of victims. The show will be opened by the Right Hon. John Burns, M.P., President of the Local Government Board, at the Art Gallery, Whitechapel, on June 2nd. It is announced that while the scientific aspect of the subject will not be neglected, the Exhibition will be chiefly of a popular and educational character. By the help of diagrams, models, actual specimens, and other means, the nature of the disease will as far as possible be impressed upon visitors. The medical profession will cordially approve this practical attempt to fight the enemy, especially as the power of such exhibitions upon the popular mind has been abundantly proved in America, and more recently by Lady Aberdeen's campaign in Ireland. One important fact about the forthcoming Exhibition is that no charge will be made for admission. further details can be obtained from the Organising Secretary, Dr. H. Hammond-Smith, 20 Hanover Square, London, W.

### The Indian Medical Service.

An interesting correspondence between the Secretary of State for India and the Governor-General of India with reference to the taking of measures for promoting the growth of an independent medical profession in India has just been published. Lord Morley, in August, 1907, called the attention of the Governor-General to a despatch of Lord George Hamilton in 1900, which expressed the opinion that it would be of great benefit to India generally that medical men should establish themselves in private practice in the country in the same way as they do in other parts of His Majesty's Empire without entering the Medical Service connected with the Army. The government of India, after a long investigation of the subject, have arrived at the conclusion that the advance in the direction indicated in the Secretary of State's despatch must be gradual, and should be made only as really qualified candidates become available in India, while a sufficient number of civil appointments should be reserved to provide for the economical employment of the war reserve of the Indian Medical Service, while it seems somewhat anomalous that nearly all the civil practitioners in India are drawn from the military medical service, there are two considerations which should carry great weight in an attempt to upset the arrangement. The first is that wider experience gained by military doctors in civil employ prevents them from "rusting," and this is of incalculable benefit to the Army; and the second is that the prospect of civil employment, with its enhanced remuneration, attracts a number of the best intellects in the profession to a service which might otherwise be none too popular. The popularity of the Indian Medical Service has been severely tried by many recent changes, and we are bound to warn Lord Morley that any hurried or ill-considered measures may seriously affect what has hitherto been considered as one of the best openings for the talent of the profession.

### The Bacillus of Whooping-Cough.

It is not a little curious that the identity of the micro-organism of so common a disease as whooping-cough has not been absolutely established. The recent researches of Klimento, however, appear to have confirmed the organism obtained in pure culture by Bordet and Gengon in the year 1906. The bacillus in question is small and short, with rounded ends; it stains feebly, and when stained with carbol methylene blue it shows polar granules. It is non-motile, aerobic, and of feeble growth, on a special medium of glycerin, potato, gelatin and blood. After several generations, however, it acquires the power of growing fairly well on other media. It appears in large numbers in the sputum, almost in pure culture during the early catarrhal stage and a few days after the whoop is established, that is to say, at the period when it is important, and at the same time most difficult to make a diagnosis. In later stages of the disease the bacillus gradually disappears, being crowded out by other organisms, notably that of influenza. Intratracheal injection in monkeys and young puppies gave rise to a malady resembling whooping-cough without the whoop, and the specific organism could always be recovered from the nasal mucous membrane, and in some cases from the lungs and blood. Out of 76 human cases the organism was cultivated only in five early cases; but it was found in stained preparation in about 80 per cent. The evidence of the identification of the specific pathogenic bacillus probably appears to be almost, if not quite, complete. It is to be hoped that further investigations will lead to the discovery of some remedy for this fatal scourge of modern civilisation.

### Consumptives as Neighbours.

THE preaching of the infectivity of tuberculosis has as its inevitable sequel an increasing dread of proximity of the disease. In Ireland it would appear that the public are at last learning that tuberculosis is infective, since, if accounts are true, consumptive patients are in some parts of the country treated almost as lepers. It is difficult to carry conviction that the disease is not communicated, if certain very simple rules be followed, though such is, of course, the fact. The fear of infection has recently shown itself in the strong opposition shown by the inhabitants of Sutton and Dalkey, two seaside villages near Dublin, to the conversion of disused coastguard stations into socalled "Health Homes" by the Women's National Health Association. It is natural, in the present state of public feeling-or public ignorance-that the proximity of such institutions should depress the value of property, and we cannot wonder that property owners should therefore object. cannot, however, believe that any injury to the public health would result, so long as such "homes" are properly managed. It is true the public are left in doubt as to the exact use to which the homes are to be put, and a little more frankness on this point might have smoothed the path of the Association. The Association is doing such excellent work that it is a pity it should be hampered by misunderstanding.

Mercer's and the Orthopædic Hospitals Bazaar.

By the time this article is in print, his Excellency the Lord Lieutenant will have declared open the large Bazaar which is being held this week in Dublin in aid of Mercer's and the Orthopædic Hospitals. The Bazaar promises to be a high success, and it is reported that it will provide attractions of all kinds on a scale which was not attempted even at the many large bazaars for which Dublin was so celebrated some years ago. The Bazaar will be held, as is usual with such functions, at the Royal Dublin Societies' premises at Ball's Bridge, and they have been very fully decorated for the occasion. The proceeds of the Bazaar will be divided between the two hospitals mentioned above, and we are sure that each one of our readers will wish that the funds of these most deserving institutions may largely benefit by the enterprise. At the moment we write one thing alone seems to be needed, and of that there seems to be good promise. On several former occasions wet weather has proved a source of considerable loss to the promoters, but on this occasion the elements promise to be different. We hope that our country readers will be able to patronise the Bazaar in large numbers, and will do what they can to benefit the funds of the two hospitals.

A Hint for the Mental Hospital.

It is a sound principle before making a start in a fresh undertaking to review carefully the experiences of others in a similar direction. That attitude, we understand, is being adopted by the Asylums Committee of the London County Council, at the suggestion of Dr. Henry Maudsley. As readers know, our confrère has generously contributed £30,000 towards the special mental hospital which they have agreed to build, and he has recently advised the Council to inspect the Berlin and Munich hospitals before completing their scheme. The wisdom of such a step is obvious, and it is understood the Asylums Committee will advise the Council to despatch an official to Germany and to other places where any useful information is likely to be gained. The importance of the attempt to treat mental diseases in their early stage is so supremely great that it would be a pity to waste time and energy in acquiring experiences that can readily be guarded against by avoiding the pitfalls that have been disclosed by previous explorers.

### PERSONAL.

Dr. EDWARD LIVEING has resigned the office of Registrar to the Royal College of Physicians, a post he has occupied for the last twenty years. At the meeting of the Council last week a resolution was unanimously passed recording the faithful and efficient manner in which Dr. Liveing had discharged the duties of his office.

THE Danish Royal Scientific Society has admitted as a foreign member Dr. Dreyer, Professor of Pathology in the University of Oxford.

THE new out-patients' department at the Royal Portsmouth Hospital was opened on May 11th. This department has been built at a cost of £4,000, given by Mr. Woolmer White, of Havant.

At a meeting of the Welsh University Court, held at Mold on May 14th, Sir Isambard Owen was again re-elected Senior Deputy Chancellor, and Sir John Williams was elected Junior Deputy Chancellor.

The fifty-seventh Annual Meeting of the Governors of the Hospital for Sick Children, Great Ormond Street, was held at the hospital on May 13th, the Duke of Fife, President, in the chair. The income for the year was £24,188, and the expenditure £23,474. The midsummer fair and  $f\hat{c}te$  at Olympia will be opened on June 23rd.

THE seventy-seventh Annual Meeting of the British Medical Association will be held at Belfast from July 23rd to July 37st, 1909. The President-elect is Sir William Whitla, M.D., LL.D., Professor of Materia Medica and Therapeutics, Queen's College, Belfast. The Presidential Address will be given by him on July 27th.

THE Address in Medicine will be given by Dr. Robert W. Philip, M.D., F.R.C.P.Edin., Physician to the Royal Infirmary, Edinburgh, and the Address in Surgery by Mr. A. E. J. Barker, F.R.C.S., Professor of Surgery, University College, London.

SIR JOHN W. BYERS, M.D., Professor of Midwifery and Diseases of Women, Queen's College, Belfast, will give the Address in Obstetrics, and the popular Lecture will be delivered by Dr. J. A. Macdonald, Physician to the Taunton and Somerset Hospital, Chairman of the Representative Meetings.

SINCE the unanimous election of Dr. R. Arthur Prichard, of Conway, as the Chairman of the Carnarvonshire County Council, a widespread movement has been initiated to present to him a public testimonial in recognition of his long and honourable career in the public service of North Wales. It is proposed that the testimonial shall take the form of an address and a motor-car suitable for his practice.

At the invitation of the Lord Mayor of Leeds (Alderman F. J. Kitson) a number of local gentlemen interested in the Health Congress, to be held in Leeds during the third week in July, met at the Town Hall on May 18th to arrange for the entertainment of the Royal Sanitary Institute and the Royal Institute of Public Health.

THE Annual Dinner of the Pharmaceutical Society of Great Britain was held on May 18th at the Holborn Restaurant, under the presidency of Mr. J. Rymer Young. Among those present were Viscount Hill, the Right Hon. Thos. Lough, M.P., Sir Dyce Duckworth, Mr. T. H. Idris, M.P., Mr. R. Winfrey, M.P., Mr. P. Snowden, M.P., and Mr. W. S. Glyn Jones.

THE MAYOR OF NEWPORT (Mr. Graham White) was on Wednesday honoured by his colleagues of the British Dental Association at the annual meeting of the South Wales Branch at Llanelly by the presentation of a silver salver to commemorate his appointment as the first dental mayor in South Wales.

### A CLINICAL LECTURE

ON

### THE FEEBLE-MINDED AND THEIR CARE. (a)

By GEORGE H. SAVAGE, M.D., F.R.C.P.Lond.,

Consulting Physician and Lecturer on Mental Diseases, Guy's Hospital; Consulting Physician to Earlswood Asylum, &c.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

ANOTHER point is that injuries may arrest development, but you must be very careful in analysing the history of the injury. I think there are very few children who have not had injuries to the head. A mother discovers that her child is weak-minded, and sets out hunting for a cause. I always think of my old teacher, Sir William Gull, when I was propounding something or other. He said, "Savages and lunatics explain; wise men investigate." And one finds it easy to explain by a fall on the head things which have no relationship to it whatever. There is no doubt that certain feeble-minded individuals owe their feeble-mindedness to inability to develop, due to opiates or a little gin given to keep them quiet. I am sure I have seen cases of that kind. Sometimes there are individuals who overgrow their nervous system and never regain it. It has been said of giants that they are like tall houses, the top storey is used as an attic. At all events, I meet with these tall individuals who outgrow their nervous system or nervous power, and are permanently weak. I suppose that every month a huge lad of 15 or 16 years of age comes into my consulting-room, and, seeing it has a door of about 6ft., he has to stoop. The majority of these never become anything but feeble-minded.

that every month a huge lad of 15 or 10 years or age comes into my consulting-room, and, seeing it has a door of about 6ft., he has to stoop. The majority of these never become anything but feeble-minded.

What are the varieties of defect in the feeble-minded? They may be general, or they may be special. It is well to look upon some such as absolutely deficient in partscof the mind. Others are permanently wanting in the power of direction of what they have. Take the simplest first. A child comes into the world an apparently normal child. He is nursed by the mother, or brought up by hand. At 18 months the mother is surprised that the child will not attempt to walk, and speech is wanting. Another six months go past, and the mother still finds the child does not walk. Yet, apparently, there is nothing wrong about the legs. It crawls rapidly about the floor, but will not walk; and is fairly good. Another 6 or 8 months go by and the child is beginning to totter about, but does not talk. It slowly begins to talk at about 3 or 4 years of age, but only imperfectly. There you have a deficiency in the most human attributes—the erect stature, and speech—as evidences of defect. I should say that they are the most important gauges of defective development which is likely to end in permanent feeble-mindedness. These children are very subject to rages, so that a little thing will upset the balance. They often are restless sleepers; not infrequently, they have night-terrors or troubles of that kind, and they are long learning the ordinary conventions of life, so that they eat clumsily, they do not keep themselves clean, they do not dress themselves well, little acts like buttoning their clothes are difficult, and yet those children are only looked upon as backward. They have learnt truth and honesty. They may have done a certain amount of book work, and here it is interesting to note the deviations that may occur. Some of these may have special ability of a limited kind. For instance, I am told that this child who could not wa

speak every language for a moment or two; if you looked at this person and addressed her in English she would look back at you and repeat your English, word for word, whether it was our English or the American variation of it. The same was true of German or French. She would repeat and reproduce words, but with no knowledge. And it is so with a certain number of these individuals, they can reproduce, but cannot develop. Now I will give an example of one who when he reached 12 or 13 years of age it was considered that he should be sent to a trade. At 14 he was apprenticed to a tailor. Daily for three years he went to work. At the end of that time his father thought he would be able to take an improver's position. He was sent to a tailor, who had not taught him, and knew nothing about the years he had served, and he was sent home at the end of 24 hours as useless. He could use the needle, and that is all he could do. He was put to another trade, that of bootmaker. He could hammer in the nails, and do little mechanical things of that sort, but give him leather and ask him to shape a boot—no, he could not do that. Yet he was a bright boy, he was a smart-looking youth, polite, and had a nice way, and it was thought that he might do for a kind of errand boy or messenger boy in a shop. No good. He was perfectly willing, but nothing could be made of him. Yet you could talk to him about most things in a way, but he could do nothing usefully.

Now and then cases of this or a similar kind are legally important. Take an example. I was asked to see a young lady who was coming into considerable property, and I was asked to report as to whether she was fit to manage her affairs. I found her a well-dressed girl of 20, who answered me in a bright way, and I thought it seemed hard lines to bring her to me. I said to her, "Do you read French?" "Yes." I gave her a French book, and asked her to lead it. I said, "Now about money matters," and at once I saw a flush over her face. "Would you mind doing a little sum?" She could not add 2 and 2 together; there was as complete a defect of understanding the relation of numbers and figures as could be imagined. I gave her a handful of money to count; she could not do it. That sort of defect is not very uncommon. Little things of that kind may interfere with the world's work, and the person may have to be considered feeble-minded. In such a case no education will benefit. Little temporary defects, which can hardly be called weak-mindedness, are amusing in a way, such as want of power of spelling ability. We find individuals everywhere who may pass muster, but are rather "soft." You not infrequently see them in villages. They form a class which, if allowed to breed, breed weak-mindedness to a certainty.

With regard to the treatment of such people, if they can be induced to do agricultural or mechanical work, well and good. It used to be thought it was good to get them into the Army and Navy, and if they were wasters it was thought to be good to get them into cavalry regiments. But the majority of them proved to be deserters before long. The training and the discipline of a service, and the discipline at sea, where they cannot get away very well, has an extremely good influence in keeping them out of mischief, and making them mechanical units. They do not become anything more than that.

more than that.

A further development, which you may say differs materially, is that of the inebriate. This matter has

<sup>(</sup>a) A Lecture delivered at the Polyclinic, London, on Thursday, May 8th, 1909.

been considered by the Commission—that is, the establishment of colonies for these various people, that there should be a colony for inebriate men, for inebriate women, for epileptic youths, for epileptic adults, and for the wasters, liars, thieves, tramps, and the rest. That is all very well, but there is the other side of the matter. Since I wrote this article people have appealed to me, thinking I had influence, which I have not, because, they said, their property was being seriously injured by the establishment of colonies for the feeble-minded in their neighbourhood. And one can well understand that colonies are extremely useful, but in England it is difficult to find the right sort of place in which to put them. In Belgium there is the oldest of all colonies, a place called Gheel, "The City of the Simple," where for over 700 years the Belgians have been in the habit of sending their insane and weak-minded, and their failures. In this out-of-the-way district there is a central receiving depot, and there are 15 or 16 little villages scattered all over the place, where these people are looked after. But we have not got places like that in England, and we cannot transport them. A certain number of these people are greatly benefited by religious institutions, such as convents.

Not long ago I saw a girl who was a Roman Catholic, and there is no doubt that if she had been at large she would have got into trouble, almost certainly moral trouble, but by getting her into a well-conducted convent she was controlled. She was easily led, and I think she will probably follow the religious life and be all right. In the same way the Church Army does excellent work. And there are one or two colonies in England which are supported by private doctors. There is one in Sussex, where there are eight or ten houses on a farm of 800 or 1,000 acres, and in each of these houses there is a head, and there are several youths of feeble mind who are being directed and kept out of mischief. The whole future treatment of the feeble-minded depends on the utilisation of these colonies. In a very large number of these cases success is only partial. Moral defects are more trying to deal with. We have to recognise that there are organic liars and organic thieves, and that honesty is a thing which has to be taught. The child comes into the world with the feeling that anything it can touch is a part of itself, and it is a slow acquisition to learn that things which it can touch do not belong to it. A large number never learn it at all. What am I to do with these thieves? The Government now sends the young thief to a kind of training prison, where, for a term, he can be kept under strict discipline, and it is hoped he will reform. A certain number are reformed. But the question is whether you are to treat these feeble-minded thieves as criminals, as sinners, or as sufferers, and I think a mixture of the two is desirable. One does not want punishment to be revenge, neither does one want the person who is a sinner to feel that he is in no way responsible, for if you encourage that, you weaken all chance of improvement. Many years ago in America I attended a Prison Congress, and I was surprised to find that in that democratic country they felt it would be the best possible thing for every person who had been convicted of anything, from pilfering to being drunk more than three or four times, to be segregated for the rest of his life.

Sexual morality, the control of the sexual passions, is very much wanting in these feeble-minded. If you go to any of these homes for the feeble-minded, for women, you find a very large number of mothers of illegitimate children, and, of course, it is all-important that such individuals should be separated. You have the morally and intellectually weak, who have given way, and who are certain to become the mothers of still weaker or worse individuals.

So there are thieves who have to be punished to a certain extent, and training will have a great effect. As far as moral defects are concerned, segregation and control are essential

The treatment of the feeble-minded, so far as drunkards are concerned, is one which I have not time to speak of now. Retreats are certainly useful for those who are organically drunkards; nothing will stop that. Everything has been tried, and there are brands plucked from the burning by all sorts of means—by drugs, by

the Salvation Army, certainly by hypnotism, and by these inebriate retreats. But I think we have hardly got so far in social evolution to allow the drunkard necessarily to be put on one side. Where will you draw the line between the dipsomaniac and the habitual drunkard? There are a certain number of dipsomaniacs who are wonderful men, and it would be a pity for them to be segregated

In the training of simple-minded girls, who are simply weak-minded, the same lines must be followed which I spoke of with regard to boys—occupation, interest, and constant observation. One of the greatest dangers is that of one child teaching evil to other children. Music, drills, gymnastics, and games are very important; a simple out-of-door life and simple diet are best; the majority of these simple-minded individuals require not only simple diet but no stimulants. As long as they are under age you can do fairly well what you like with them, but when they get older and it becomes a question, if they have property, of making them Chancery patients, difficulties may arise. There are many advantages if you can make a patient a ward of the Court of Chancery. There is a girl coming into considerable property; she is feeble-minded, and nothing more. Nobody could certify her. She does not understand money or the value of things at all. If she came into her fortune almost anybody could get it away from her. But is one going to prevent her from marrying? I shall try to make her a ward of Court, so that it would be a misdemeanour to approach her with the idea of marriage, without the consent of the Court, which, of course, would not be given.

Various avocations have been suggested for them. The present rage is to make every feeble-minded boy a poultry farmer or a fruit farmer. But there is a limit to that. If you get a boy that takes a real interest in it and makes his own hen-coops, it is all right; but he is not trustworthy. He falls into the lines of that definition which I gave. He could not, alone and unaided, earn a living for himself. In the case of these weak-minded individuals, one thing which is constantly tried and will be tried to the end, if they are wealthy, is that they will be sent round with a tutor to see the world. In some cases it does them good. One result I have seen from that has been satisfactory, but it cannot be advised—that is, one of these young men had a serious illness and married the nurse.

Next with regard to epileptics. There is no doubt about the gravity of the disease, especially if it commences in quite early life. There are several epileptic school colonies now. There is one at Lingfield, of which I am Honorary Physician. They have got several hundred children who are epileptic, but neither im-becile nor idiotic. They are educable children children from various parishes all over England. They are sent down at very low rates, where they have a perfectly good life. But you will never make them more than feeble-minded. They all have to be seen by me before they go to the colony, for me to decide that they will improve by education. First, they are living in houses of only one floor, so that they cannot fall downstairs; there are no dangers from lakes, ponds, or railways. Their diet is almost purely vegetarian; no stimulants. Their senses are educated more than their so-called mind. They have object-lessons and drawings; they draw and describe. They are carefully drilled; they have music and musical drill, and are taught singing and harmony. They have a certain amount of bromide, but not much; the quantity is reduced compared with the quantity they were taking before they were admitted. The fits decrease, and the children improve in a remarkable way. They will never become normal. The overseer says: "They will go on working as long as I am looking after them, but when I stop looking they stop working." When they have to leave school they are additions to the permanently feeble-minded class; they are individuals who have to go either to the workhouse or to the infirmary. The destination is that the epileptic group of feeble-minded is a very unfortunate one.

So there is a certain class of feeble-minded people who will never be anything else; but there are grades and degrees of feeble-mindedness. There are these weak-minded epileptics who are taught to do certain

mechanical things, and lead fairly happy and certainly healthy lives under restricting conditions. We have also to remember that there are such things as backward or even feeble-minded children who may suddenly ward or even teeble-minded childles was and become normal. Therefore another difficulty arises, and one must hesitate in condemning every feeble-minded child as permanently feeble-mined. It has been said that some of our greatest imaginative poets have been dullards at school, and have been looked upon rather as fools; and I remember one boy whose salvation depended on a fit. He was a weak-minded youth, and his father gave him up as hopeless. He had a series of epileptic fits, which seemed to break the spell, and in a few years he was in advance of his fellows, having had no more fits. There are very few backward children who really become normal, and the essential of all things is early recognition and early treatment.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for nest week will be by Professor H. Huchard, M.D., of the Faculty of Medicine, Paris. Subject: The Clinical Forms of Arterio-Sclerosis."

### ORIGINAL PAPERS.

### SUPRA-PUBIC PROSTATECTOMY. (a)

By G. P. NEWBOLT, F.R.C.S.Eng.,

Surgeon, Royal Southern Hospital, Liverpool,

In dealing with the subject of supra-pubic prostatectomy, I do not wish to enter into the question of whose operation it is, whether Freyer's or M'Gill's. (a) There is no doubt that it is a good operation, and that Freyer brought it into the position which it now holds in surgery. Again, I have practically no experience of perincal prostatectomy or of the combined operations of supra-public and perineal prostatectomy, and shall not, therefore, deal with them. My first point is, Under what circumstances should the operation of supra-public prostatectomy be advised? and before deciding this we have to consider the questions of mortality and of the actual relief given. Now, the mortality in Freyer's cases is low, about 8 per cent.; but he has been fortunate, and is an expert in this branch of surgery. I do not think the general surgeon who only does these operations occasionally will get the same results as Freyer has published. Escat gives a mortality of 18 per cent. in 164 cases, which I should think is likely to be the general average, unless the cases are selected. Personally, I have not been the cases are selected. Tersolarly, I have been heavy. Therefore, in advising people concerning this operation, I have put the facts plainly before them, and in several cases they have preferred to put up with present discomfort rather than run the risks involved.

I am speaking now more especially of cases in which the trouble has been rather an inconvenience than anything else. I have operated upon nine cases, and three died as a result of the operation; these were all hospital cases, and with one exception men in a very poor and broken-down condition. Death resulted from hæmorrhage in one and from uræmia in the other two. Another case came back eighteen months later with cystitis and stone, and died from bronchitis after a second cystotomy; four others were in good health some time after operation, and the fifth is convalescing. I have found no difficulty in carrying out the operation practised by Freyer, and whenever a definitely enlarged prostate has been present have got it out easily. The larger the prostatic mass, the more easily it enucleates: those which give trouble are the little, hard, fibrous ones, which are not suitable for removal by the abdominal routeonly it is not always easy to be sure of their nature beforehand. There is no doubt that, if possible, the

patient should be under strict observation for some time before one performs the operation. His urine should be tested carefully and the percentage of urea determined. It is also as well to wash the bladder out if cystitis be present. If there is difficulty in getting the catheter in, it may be better to drain suprapubically until things have quieted down.

Now, though I have so far only operated upon some nine cases, yet during the last few years I have seen a large number of cases of enlarged prostate, and from them have gained a good deal of information. One point is this: that, given a man with an enlarged prostate of some years' duration, and giving rise to some measure of obstruction, his life is an exceedingly uncertain one, and the following are good examples of this:-

(t) Six months ago I saw a man, æt. 63, in consulta-tion with a view to prostatectomy. He had had retention several times, and there was a large amount of residual urine, but he could pass his urine himself in the intervals of his attacks. He had an enormous prostate, which could be easily felt bimanually. His urine was acid (sp. gr. 1010), and his pulse was regular. Altogether he seemed to be a very suitable case for operation, and was admitted for that purpose; but uræmic symptoms came on directly after admission, and he died nine days after my first seeing him. It was a typical case for operation as far as the prostate was concerned.

(2) Three years ago, I saw a gentleman, æt. 72, who had suffered from retention for some five weeks. There was difficulty in getting a catheter in. However, I happened to have a coudé which passed easily, and he was content with this, and would not entertain any operation. Six weeks later I heard he died somewhat suddenly.

(3) Five years ago a man was admitted under my care to the Royal Southern Hospital with hæmaturia and retention from an enlarged prostate. His urine was drawn off, and he was taught to pass a soft catheter. He died suddenly in the night, half an hour after he

had emptied his bladder with the catheter.

Besides these examples, I have had a number of cases sent into hospital under my care with a view to operation which have developed uramic symptoms, and died of advanced kidney disease. The man, therefore, who gets retention early in his disease, and whose operation is done whilst his kidneys are healthy, is lucky inasmuch as he has a good chance of recovery; but the operation on a hospital patient with advanced kidney disease is about as promising as that performe! in the old days on a case of strangulated hernia of five or six days' duration. I have often congratulated myself on the fact that I did not touch either of the three patients whose cases I have quoted, for without doubt they all would have died soon afterwards. The result would naturally have been put down to the operation. An early operation would most probably have prolonged life, and, if so, most certainly would have made it more comfortable. But there is another side to the picture. A man may have an enlarged prostate giving rise to much inconvenience, and yet he may go on for years, dying eventually from some other complaint. A good instance of what an elderly man may stand is the following:—Some years ago I was awakened at 2 a.m. by the strains of a military band returning from Aldershot. With difficulty I got to sleep again, and urgent knocks at my front door failed to rouse me. Not until my telephone bell rang at 7 a.m. did I respond to an urgent call to attend to the bandmaster of the band which had so rudely disturbed my slumbers. I found him suffering from acute retention, and bleeding from attempts made to catheterise him. Supra-pubic aspiration at once relieved him, and I was able to pass a catheter later on. Two years ago I again saw this man (who was then 78) for a second attack of retention. After a week's catheterisation he again recovered control, and is well at present. Now, he is not a very healthy-looking man; he suffers from bronchitis, and it would be a risky thing to remove his prostate.

It is a curious thing how tolerant the bladders and

urethræ of some men are, whilst those of others are offended at the slightest liberty. For instance, one man gets gonorrhœa, which gives endless trouble and finally culminates in a prolonged gleet, a stricture, or a stiff joint; another speedily gets rid of his trouble and suffers no after-effects. The same with an enlarged prostate: one man gets cystitis after the passage of his catheter, though he has taken the usual precautions to keep it aseptic; the other moistens his catheter with his spittle, passes it, and is no whit the worse. Again, the hospital patient is usually in a worse condition than the man of means; he has been more exposed and has roughed it more. As an instance of this, I may mention three cases of diabetic gangrene for which I amputated through the middle of the thigh. The two hospital patients died; the private patient made a good recovery, though the other foot had been operated upon and though there was a very large amount of sugar in his urine. It

(t) A prostate weighing 5\(\frac{3}{2}\) ounces removed from a man, \(\pi\)t. 60\(\frac{1}{2}\), met on-cerned.
The patient remains well as far as his bladder is concerned.

appears to me, therefore, that though we may lay down rules for advising these patients, yet we have to take all the surroundings into consideration. What, then, are the indications for operation?

- (1) Complete retention and catheter life in an otherwise healthy man.
- (2) Frequency of micturition rendering life unbear-
- able and coming on at an early age—say at 60.

  (3) Hæmorrhage from the prostate, profuse in
- character and recurring at intervals.

  (4) Occasional retention, with difficulty in the passage of, or inability to pass, a catheter.

In all of these conditions I should strongly advise operation unless some other disease contra-indicated it.

In cases in which there is pain and discomfort in the perinæum or where there is occasional dribbling of urine I should let the patient decide whether he will have what I tell him is a serious operation done. should only advise it if he were in good condition, with normal urine.

I have advised against operation where there was I have advised against operation where that was frequency in the daytime in a clergyman, but not sufficient to prevent his doing his duties, and no necessity for the use of a catheter. Speaking generally, I do not believe in operating if there is a suspicion of malignant disease.

This brings us to the question of the diagnosis of malignant from simple enlargement of the prostate. This is often a matter of great difficulty. In the first place, malignant disease is far more common than is usually supposed, and though, when it was a question of simple treatment with a catheter,

etc., a mistake was not a very serious matter, nowadays an operation done under these circumstances will lead to great disappontment. I should put the symptoms of malignancy down as follows:-Frequency of micturition, pain, hæmaturia, and loss of flesh, with the presence of a hard, enlarged, and possibly fixed prostate. Persistent pain in the lumbar region or sciatica is always suspicious, and we naturally examine the rectum to try and find the cause. prostate is nodulated or enlarged it looks suspicious, and we await developments. A very good instance of this occurred in a patient whom I saw with a double hernia and with interest leads to the control of the contr with intense lumbar pain. Examina-tion per rectum revealed nothing, no medicine relieved him (he was under a physician), and I was persuaded against my better judgment to do a radical cure on one of the herniæ, which it was thought might be the cause of the pain. His lumbar pain persisted, and a second rectal examination revealed a hard, somewhat fixed prostate, quite different from the condition found at the examination two months previously. He developed sciatica and died soon after. Another patient had sciatica, for which he was treated until an examination per rectum cleared up the diagnosis. The case of a man named Miles P. is one of the most typical I have seen. He was admitted with retention and a history of attacks of hæmaturia and pain in the back. On examination he had a large hard prostate fixed on the left side, and a cystoscopic ex-amination showed a white, glisten-ing outgrowth from the left side of the prostate projecting into the bladder. No operation was suggested, but he was taught to pass a catheter. Later on in the disease

the inguinal and also the femoral glands became enlarged. Now, operation in these cases is not going to bring any surgeon much credit, and the final state is worse, in my opinion, than if they are left alone, unless you can get cases in which the whole disease may be removed—and these must be very rare indeed. The picture of a growth fungating through a suprapublic wound which has broken down, with the concomitant dribbling of urine, is a thing to be avoided if possible. If in doubt, I should advise frequent examination and waiting, for the disease will very soon reveal itself, as it did in the case of the man whose hernia I operated upon; or an exploratory perineal operation with a view to removal by this route after H. H. Young's method.

With regard to the operation itself, Freyer's description can be read in his own words, and I shall only take some of the points which have impressed me. In all supra-pubic cystotomies the proper distension of the bladder simplifies matters immensely; whether it is done with air or boracic lotion I don't think matters. The Trendelenberg position helps (and here I may say that these remarks are intended more for the gentlemen who only occasionally do a bladder operation than for my expert surgical friends). When the bladder comes well up from behind the pubes it is

well up from behind the pubes it is easy to open it with a thrust of the knife, and thus time is saved—an important item in operations on old people. The edges of the bladder are secured with silkworm gut sutures to which forceps are attached, so (5) P that no forceps are put on the edges of the bladder itself. These sutures hold the bladder up and also serve as retractors. One next feels for the point of the catheter which has been passed, and determines the nature of the prostate to be enucleated. determines the nature of the prostate to be enucleated. So far I have chiefly used my finger-nail, but have found that, unless it speedily enucleates, the nail gets soft and rather handicaps one, especially with the little, hard, fibrous ones. I have also used curved scissors to snip away some pieces of tissue which my nail would not tear. I usually start the enucleation from the right side, working towards the left and using the right index finger. In most of my specimens a piece of membranous urethra shows; but I think the less of this removed the better, as otherwise one gets

(4) This specimen shows a piece of membranous urethra hanging down from the prostate. The operation was performed for profuse hæmorrhage arising from an uleer on the part projecting into the bladder. He is well four years after operation.

after-trouble. In the last case I did, no membranous urethra was removed. The gloved finger of the left hand in the rectum is of the greatest assistance. After separating the tumour, it is seized with forceps and drawn up to the opening in the bladder. If large, the opening must be extended; it is far better to close it after than risk bruising the edges and causing sloughing. Occasionally there is hæmorrhage, and it is as well to compress the cavity left by pressure with the fingers in the rectum from below and counterpressure from above. If this fails, hot saline may be of use; and failing this the bladder must be packed with gauze. These patients won't stand hæmorrhage, and I unfortunately lost a case from this cause. The prostate in question enucleated quickly and easily, and perhaps the fact that I wished to do a rapid operation led to disaster. I got the operation over and sent the patient back to the ward, where he commenced to bleed. My house-surgeon controlled the bleeding by packing the bladder and transfusing; but the shock of operation, with the hæmorrhage added, proved too much for my patient, and he sank some eight hours after operation. I feel that if he had

(5) Portions of a little, hard, fibrous prostate, difficult to remove.

been kept a little longer in the theatre this might not have happened. When satisfied that hæmorrhage has been controlled, all that is necessary is to fix a large rubber tube in the bladder and wash through with hot saline by means of a soft catheter passed down the urethra. By seeing that the tube fits the hole in the bladder accurately, the patient can be kept fairly dry. Wood wool makes the most comfortable dressing. At first I tried sponges frequently changed, but they speedily became ammoniacal, and the edges of the wound got encrusted with phosphates. The tube may be removed from the bladder about the fourth day, and irrigation kept up through a soft catheter passed down the urethra. Patients begin to pass urine naturally about the tenth day, and the wound closes any time after the third week In my opinion, the stouter the man the more difficult the operation, especially if, as is

often the case, he has a big scrotal hernia. The hard, fibrous prostate is the difficult one to remove; moreover, the result is not so good, as a cavity remains which does not contract like the one left by a clean enucleation, and the patient is liable to get a phosphatic deposit unless he is careful. This occurred in one of my cases, the patient returning eighteen months later with a phosphatic stone in his bladder. (To be concluded in our next.)

### Metropolitan Hospital.

THE festival dinner in aid of the Metro-The festival dinner in aid of the Metropolitan Hospital, Kingsland Road, was held on May 21st, at the Whitehall Rooms. Lord Duncannon presided, and among those present were Lord Howard de Walden, Mr. Henry Wagner, Mr. W. G. Raphael, Major S. Weil, Mr. C. J. Thomas, and Professor Hermann Gollancz. The chairman said that they must remember

that the institution was not only a poor one, but that it was in a poor district. The average expenditure amounted to £14,000, and the assured income from investments came to only a little over £500. There were in the hospital 113 beds, and on an average 105 had been constantly occupied during the past year. More than 300 patients had been sent to convalescent homes, and about the same number had been helped to procure surgical and other appliances. This year the hospital had to make special demands for repairs to bring it up to modern requirements. The cost was estimated at £8,000, and, in addition to the sum required for the ordinary working of the institution, there were also needed an isolation ward and a new nurses' home. It was announced that the total sum given in subscriptions at the dinner was £4,852 58.

An Anti-Tuberculosis Congress was opened at Athens on May 19th, the Crown Prince presiding.

### THE TREATMENT OF CHOLERA. (a)

By Major LEONARD ROGERS, M.D.Lond., F.R.C.P.Lond., F.R.C.S.,

Professor of Pathology, University of Calcutta

In view of the fact that the case mortality of cholera has certainly not been reduced in India during the last seventy years, the treatment adopted by older Indian writers is of great importance. I have carefully studied them, but can here only give a very brief summary. In the days of Annesley and Twining (1832) mary. In the days of Annesley and Twining (1832) copious bleedings and violent purges were universally used in all conditions thought to be inflammatory, which included cholera. Yet Twining, who bled so much in fevers, warns against its dangers in all but the very early stages of cholera. Moreover, the inevitable 20 to 30-grain doses of calomel was always tempered by full doses of opium in cholera by the physicians of that time. With these exceptions their treatment of the disease scarcely differed from that which has prevailed up to the present day. Thirty years later in the time of Morehead, Goodeve, and Macnamara, bleeding and large doses of calomel had been finally abandoned, while opium remained the sheet anchor in the precollapse stage of cholera, being now combined with astringents, such as acetate of lead and dilute acids. In 1893 Wall's book on the subject appeared, and his great experience emphatically endorsed the same line of treatment, while he also enthusiastically advocated the use of saline injections, which the antiseptic era had now rendered much safer than when they were first introduced by Mackintosh and Latta in Edinburgh in 1831.

THE GREAT VALUE OF OPIUM.

The one fact which stands out preminently from their writings is the universal opinion as to the great value of large doses of opium in cholera, the present comparative neglect of which is, I think, a retrograde step. In the premonitory diarrhœa there is general agreement that opium can cut short the disease, while in the more advanced stage of copious evacuations Wall advises tr. opii min. 12 with acid suph. dil. min. 10, to be repeated in two hours if necessary. If rejected by the stomach he gave 12 minims of the liquid extract of opium subcutaneously, greatly preferring this to morphia, and found that in a large number of cases it prevented collapse after the onset of which it is too late for this remedy. Goodeve gave two grains of opium, or 40 minims of laudanum, while Macnamara used opium with acetate of lead or dilute sulphuric acid. For semetime past I have been giving morphia hypodermically to every other cholera patient admitted within the first two days of the disease with, I think, some benefit, but have not seen any approach to the invariable cures recently reported from Sylhet. Regarding the use of calomel in small doses there is much greater difference of opinion, Goodeve stating that it got its reputation owing to its doing no harm, while Wall condemns it as being altogether injurious. It is possible that the drug may help to re-establish the flow of bile as Annesley maintained, but I doubt if this is sufficient to counteract its dangerous purgative effects. If given at all it should be in \( \frac{1}{2} \) grain doses, repeated several

Camphor has also been recommended as a stimulant, especially in Paris, but its value is at least doubtful. The value of the long catalogue of other drugs which have been extolled is probably in inverse ratio to their number. The question of the use of alcohol in cholera is a very vexed one, many observers from Corgyn to Macnamara utterly condemning it, the lastnamed considering it to be "both theoretically and practically an unmitigated evil." Goodeve and Wall, bowever continuous recommend it in small does. The however, cautiously recommend it in small doses. The great objection to it appears to me to be its tendency to increase the vaso-motor paralysis, so that it is very rarely advisable in native patients, and only occasionally in Europeans who have been accustomed to its regular use. When given its effects on the pulse and blood pressure should be carefully watched. Ammonia may be substituted with greater safety.

Once the pressure has sunk to a very low point, or

(a) Abstract of Paper read before the Cholera Section, Indian Medical Congress, Bombay, February, 1909.

complete collapse has ensued, drugs are not only useless, because not absorbed, but become positively dangerous, as they accumulate in the alimentary tract, and later may enter the circulation during the stage of reaction in undesirable quantities. Either nothing but frequently repeated small quantities of water or ice may be administered, and the patient left to take his chance; or active measures to rapidly restore the ebbing circulation must be adopted, the following methods being available in the latter alternative. When the violence of the initial diarrhoea has abated. leaving a pulse of fair volume and a blood pressure of from 60 to 80 min. in natives, saline enemata of from one-half to one pint should be administered every two to four hours. In mild cases this will suffice to tide the patient over the threatened collapse, or to prevent its recurrence after revival by intravenous transfusion. If relied on a most careful watch must be kept for any further sinking of the pulse necessitating more active measures, because marked collapse may ensue at any moment, especially if renewed watery evacuations occur.
SUBCUTANEOUS INJECTIONS.

The next most simple measure is subcutaneous injections over the chest, axilla, or thighs, which appears to have been introduced by Wall, and has been largely used in India during recent years. About half a pint is usually injected in one or more places, and if any pulse remains it is rapidly absorbed. are two serious objections to this method. owing to the low vitality of the tissues in cholera, abscesses frequently follow in spite of great care in the administration. Secondly, my observations on the serum and specific gravity of the blood before and after cholera transfusion show that in any case requiring saline injections it is generally useless to administer less than three pints, while four are usually required to reduce the concentration of the blood to, or better a little below, the normal point; an amount which cannot conveniently be given subcutaneously. In all severe cases, therefore, we have to fall back on the use of intravenous saline injections, which unfortunately require considerable technical skill and time, seriously limiting their general applicability in India. Moreover, although the immediate effects in restoring the circulation and relieving the cyanosis, cramps and restlessness are simply marvellous: yet the ultimate results have hitherto been extremely disappointing, for only too often the diarrhea rapidly recurs, all the improvement being frequently lost within a few hours. Wall rightly insists that it should be repeated again and again, and mentions should be repeated again and again, and mentions success being attained after six transfusions, but admits that as many as 70 per cent. of his patients died. Goodeve remarks that "owing to no means having been found to keep the fluid in the vessels the method just missed being a great and glorious discovery." In my own experience, in conjunction with Captain J. W. D. Megaw, I.M.S., this method produced only a slight reduction in the mortality on account of the same recurrence of the diarrhoea which has baffled all previous workers, and intravenous injections were once more almost entirely abandoned at the Calcutta Medical College Hospital.

It then occurred to me that the failure might be due to diluting the concentrated blood by the normal saline solution (o6 per cent. NaCl.) which has nearly always been used, and that what was required was to replace the lost fluid, and at the same time maintain a high percentage of salt in the blood, which would tend to cause the osmotic current to carry fluid into the vessels, rather than allow it to escape from them. The remarkable success which has attended the intravenous injections of hypertonic salt solutions in cholera has already been recorded, and time will only permit me to mention that among 175 cases treated in the first nine months of 1908, during the very virulent epidemic then prevailing, the mortality, including all late moribund and complicated cases, has been only 33 per cent. or but little more than half the rate of several previous years, and that too although it was frequently impossible to transfuse as many as one should have liked. I must not omit to mention that all the hard work of carrying out this method has fallen on Captain Maxwell Mackelvie, I.M.S., who deserves the fullest credit for his successful labours. Favourable reports of its use in a few cases have also reached me from several quarters.

INTRAVENOUS TRANSFUSION.

The continuous method of intravenous transfusion of Cox should also be referred to, as it is reported to have given good results in his hands in Hong Kong. With the hypertonic solution used in Calcutta, namely, 120 grains of sodium chloride (with 3 grains of calcium chloride, owing to the frequent great decrease of the coagulability of the blood) to one pint, a single rapid injection of four pints usually suffices to permanently tide over the collapse stage, but in some cases it has to be repeated.

Owing to the technical difficulties of intravenous

Owing to the technical difficulties of intravenous transfusion rendering it inapplicable in India except in well-equipped and staffed hospitals I have devised a cannula for easy and rapid intraperitoneal injections, which has been used by the assistant surgeons and hospital assistants at the Campbell Hospital, Calcutta, in a temporary mat shed with earth floor, with an encouraging degree of success, under the superintendence of Major J. C. Vaughan, I.M.S., to whom I am greatly indebted for so kindly giving the method a trial under conditions which afforded a reliable guide to its general feasibility in India. It consists of a small silver-plated steel tube, with one end sharpened like a cork borer and a flange two inches above to prevent it slipping in too far. A blunt stiletto suffices for cleaning the tube when necessary. A small incision is made with a tenotome, or other narrow-bladed knife, through the skin and fascia of the anterior abdominal wall just below the navel, where the peritoneum is adherent. The tube is inserted into the wound, and with a boring movement can readily be made to enter the peritoneal cavity without any chance of injuring the intestines. From 3 to 4 pints can readily be run through in about ten minutes, the little operation being thus much quicker and easier than intravenous injections. If any pulse remain, the fluid is rapidly absorbed, so that it can be used in all but absolutely moribund patients, in whom immediate intravenous injection is essential. An abdominal binder applied after the injection which both slightly raises the blood pressure and facilitates absorption. The injections can easily be repeated through the same perforation, a superficial stitch and some collodion on cotton wool being afterwards applied. When a large number of cases have to be treated with a small staff, this method promises to be of great value.

TREATMENT OF URÆMIA.

Lastly, a few words remain to be said on the treatment of uramia. The post-mortem renal transfusions already mentioned led me to watch the blood pressure day by day in the reaction stage of cholera patients, with the result of showing that this complication most commonly occurs when the blood pressure does not rise above 100 m.m., while at higher ones urine is readily excreted. One man, with deep stertorous breathing of 42 to the minute and almost absolute unconsciousness, made a good recovery on his blood pressure being forced up from a little under 100 to 110 by hypodermic injections of adrenal and digitalin. Hot-air baths have also been of value once full reaction had been attained by large transfusions. Cupping over the kidneys should never be neglected.

In the time at disposal I have only been able to touch on the salient features of the treatment of this appalling disease. I venture, however, to hope that the hypertonic transfusion in collapse, and blood-pressure-raising treatment of the uræmia may prove sufficiently successful in other hands to do something towards removing the, not altogether unjust say, however, that it appears to me the profession in India require a little gentle stimulation in this direction." It would seem as if we had almost abandoned ourselves to despair in the matter of the treatment of cholera: doubtless, the task is beset with difficulties, but this should not depress, but rather stimulate, research, where the good of our fellows and the honour of our profession are so deeply concerned. The solution of the question, I repeat, is one which preeminently devolves upon men living in the endemic

area of cholera, and it is to us, therefore, that the profession in Europe naturally turn for information on these matters.

## THE ESSENTIALS OF PHYSIOLOGICAL HISTORY.

By DAVID FRASER HARRIS, M.D., B.Sc.Lond.,

Lecturer on Physiology in the University of Birmingham.

ABSTRACT OF LECTURE I.

The first of a course of three lectures on "The Essentials of Physiological History" was delivered in the Medical Theatre of Birmingham University on Thursday, May 6th, 1909. The lecture was fully illustrated by lantern slides of portraits.

Dr. Harris said his intention was to give in each lecture a concise sketch of the history of the growth of knowledge regarding such functions as the circulation of the blood, respiration, the action of the nervous system, digestion, secretion, &c., so comprehensive that those interested in biological history could have before them the views held from the earliest times up to the present day. As regards

DISCOVERY OF THE CIRCULATION OF THE BLOOD, undoubtedly William Harvey had many forerunners, the passage of blood through the lungs from the right to the left side of the heart having been described by Michael Servetus, the Spanish theologian and martyr (1546), M. R. Columbus (1550), and Andreas Cæsalpinus (1571). The lecturer pointed out that, until the seventeenth century, the term " circulatory system " would have had no meaning. Some notions were then given of what Hippocrates, Plato, Aristotle, Praxagoras, Erasistratus and Herophilus wrote or taught about the vascular system. The ideas of Claudius Galen (130-200 A.D.) were described in detail, because the Galenical was the only physiology which the schools of Europe had for about a thousand years. Galen believed in an ebb and flow in veins, but knew that the arteries contained blood, and taught that the blood passed from the right to the left side of the heart by pores in the interventricular septum. This "Galenical doctrine of the heart" was doubted by Vesalius (1543), denied by Servetus and Columbus, and completely disproved by Harvey, both in the fifth chapter of the "De Motu," 1628, and in his "Letter

to P. M. Slegel," of Hamburg (1651).

After Galen's death no fresh light was shed upon the vascular mechanism; his writings in Greek were the scientific legacy left by the Roman Empire to European medicine. He had editors, commentators by the hundred, but no research was done until the era of the Italian Renaissance. Mundinus, of Bologna (1315), and Berengarius, of Carpi 200 years later, both wrote text-books of anatomy and dissected the human body, which latter Galen had apparently not done; but no systematic account of angeiology was given till Vesalius published his magnum opus, the "De corporis humani fabrica" (Basel, 1543). With Vesalius we enter on the modern period of anatomy, as with Harvey of physiology. Vesalius, besides describing the whole human frame by means of beautiful illustrations, displayed the valves of certain veins, and held the nonporosity of the septum, but did not know of either the "lesser" or of the systemic circulation. M. R. Columbus, in his "De re anatomica" (1559), and Servetus, in his "Christianismi restitutio" (published 1553), both describe the pulmonary transit. Servetus and his books were burned at the stake at Geneva, by the order of Calvin, in 1553. The claims of Cæsalpinus were briefly alluded to, seeing that in Italy Cæsalpinus is regarded as the dis coverer of the circulation, and because in 1878 a

commemorative marble with an inscription to that effect was unveiled in the University of Rome. Though Cæsalpinus knew a good deal regarding portions of the circulatory system, and understood the "lesser" circulation, he did not grasp the system in the way Harvey did, and he did not demonstrate it, nor, as far as one can make out, did he succeed in teaching it to any one. Professor Filippo Pacini, in a letter published in the Lancet (October 14th, 1882), makes the following confession :- " I am bound to acknowledge that the glory of having demonstrated that discovery by every kind of argument or of fact belongs unquestionably to Harvey. If Cæsalpinus and Harvey were now living, it is certain that our scientists would consider it a duty to ascribe it to Harvey; but, both being dead, it is natural that Italian scientists would attempt to claim it for Cæsalpinus, and thus it is that Italy is still called the land of the dead." Fabricius, Harvey's teacher in Padua (1537-1619), though he wrote a monograph on the valves of the veins, knew no more of the circulation than Galen.

Dr. Harris then gave an outline of the life of Harvey, remarking that he had distinguished patients (amongst them King Charles I., and the Lord Chancellor Bacon), distinguished contemporaries, correspondents and opponents. The contents of the various chapters of the "De Motu" were then epitomised, and it was seen that, besides being an anatomist, physician and physiologist, Harvey was a zoologist, a comparative morphologist, and tried to be a histologist as well. He used his "perspicillar" or simple lens, wherever he could. Not possessing the new or compound microscope, he could not see the capillaries—the tubes leading from arteries to veins, but he inferred their existence as "porosities of the lungs" and "porosities of the flesh." Harvey made the capillaries a logical necessity; Malpighi made them a histological fact. Marcellus Malpighius, in 1660 in Bologna first saw them in the lungs of the frog. Leeuwenhoek, in 1688 in Delft, discovered the systemic capillaries in the tail of the tadpole and web of frog's foot. Dr. Harris then showed how the Rev. Stephen Hales studied the physical problems of the circulation ("Hæmodynamics," 1726), his forerunners having been Lower, Borelli and Keill.

The contributions to the physiology of the circulatory system by J. C. Arantius, A. M. Valsalva and Steno, having been noted, a summary was given of the advance in knowledge during the eighteenth century up to the work of Thomas Young and John Hunter.

A rapid epitome of the chief additions made during the nineteenth century closed the lecture.

### OUT-PATIENT'S ROOM.

ROYAL FREE HOSPITAL

Treatment of Chronic Ulcer of Leg. Under the care of Mr. WILLMOTT EVANS, M.S., F.R.C.S.

Amongst the out-patients was a man, æt. 62, with an extensive ulcer on his right leg, measuring 8 in. by 7 in., and extending nearly the whole way round the limb. It was deep, and the edges were thickened and in parts sharply cut and irregular. Mr. Evans said that the diagnosis of these chronic ulcerations of the leg was by no means always easy. It is customary nowadays to diagnose most of these ulcerations as arising from varicose veins, while the diagnosis of syphilitic ulcer of the leg is restricted to those cases in which multiple punched-out ulcers are found especially near the knee. With this view Mr . Evans

totally disagreed. Of course, he recognised that the ulcers last described were syphilitic in origin, but he felt sure that a very large proportion of the ordinary chronic ulcers of the leg were also due to tertiary syphilis. He did not deny that interference of the circulation of the limb produced by varicose veins favoured greatly both the origin and persistence of syphilitic ulcers, but he considered that the syphilitic virus was the true causa causans in the condition. Success in the treatment of these cases depended, in his opinion, on the acceptance of this view. It is not difficult, he remarked, to cure these cases of chronic ulcer of the leg if the patient can be confined to bed for a number of weeks, but the problem is by no means. so simple when it is required to effect a healing of the ulcer while the patient is still pursuing his ordinary occupation. The use of Unna's zinc dressing is of occupation. The use of Unna's zinc dressing is of great value in suitable cases, as it tends to prevent the venous engorgement caused by varicose veins, but the application is tedious, and many patients do not like it. To treat these cases successfully it must be recognised that three factors are present. We have, first the syphilitic virus; secondly, the venous congestion; and, thirdly, sepsis produced by the ordinary pyogenic organisms. The syphilitic taint must be treated by mercury or potassium iodide internally. He preferred mercury or potassium iodide internally. He preferred to trust to the iodide to remove the manifestations of the disease, but he considered that mercury was essential to prevent recurrence. It is also important to recognise the beneficial effect of both mercury and iodine when applied locally. The iodine is best used for local treatment in the form of a lotion of the strength of the tincture, diluted or not with water according to the smarting effect produced. On the whole, he considered the best mode of local treatment of these chronic ulcers was by powder. Most of the organisms producing the suppuration in the ulcer failed to develop if the wound can be made perfectly dry, and this can be brought about by the use of a suitable dry powder. The powder which Mr. Evans preferred consisted of the following: 10 grains of calomel, \(\frac{1}{2}\) oz. of oxide of zinc, and \(\frac{1}{2}\) oz. of "kieselguhr." This powder is extremely absorbent, and the presence of the calomel makes it also antiseptic and gives it an anti-syphilitic power. The wound is bathed at each dressing with the iodine solu-tion, and it is then filled with the powder. At the next dressing no powder is taken away, but the moist places are again dressed in the same way, additional powder being applied. The rapidity with which the wound becomes dry depends greatly on the care with which the dressing is conducted, but generally in two or three weeks the greater part of the ulcer has become perfectly dry and ceases to secrete any discharge. crust formed is not disturbed until in course of time it is thrown off, and healthy skin is found beneath it. Occasionally it happens that the healing is not complete, a small part of the ulcerating surface still remaining; this is treated similarly, and ultimately complete recovery should follow. All this time the internal treatment is continuing, and the leg should be rested as far as possible.

### OPERATING THEATRES.

GREAT NORTHERN HOSPITAL.

OPERATION FOR ACUTE APPENDICITIS .- MR. ARTHUR EDMUNDs operated on a man, æt. 20, who had been admitted suffering from abdominal pain. The patient was taken 48 hours before admission with colicky pain in the lower part of the abdomen, and vomiting, which former continued up to the time of his arrival at the hospital. The bowels had acted on the day of the onset of the attack, but not since, though he was usually regular in that respect. On admission he had but little pain, his temperature was 100°, and the pulse only 90; indeed, on his symptoms, without examining the abdomen, the whole case seemed apparently trivial, but the abdomen was motionless at the lower part and very rigid. The diagnosis in these cases, Mr. Edmunds said, was always important, as, in spite of all that has been written, the number of cases in which opera-

tion has been delayed too long is still large. When it is possible to make the diagnosis of appendicitis an operation becomes the wisest course in the absence of operation becomes the wisest course in the absence of any conditions which would prohibit any operation, and the question to be decided is simply when the operation is to be performed. Operating upon every case of appendicitis undoubtedly, he pointed out, means operating on many cases which would have recovered, without operation, and, were it possible to differentiate with certainty the type of appendicitis from which the patient is suffering, non-operative measures might be adopted in a large number of cases. This is, however, not possible, and surprises in the shape of grave disease, combined with trivial symptoms, are common even in the practice of surgeons. of the greatest skill and experience. As to the time of the operation, there is no doubt that in the quiescent period between attacks the operation is simpler, but stage is that drainage is necessary in cases which might have recovered sufficiently for an operation to be performed in a quiescent interval and the wound completely survived. On the other hand, a certain perperformed in a quiescent interval and the wound completely sutured. On the other hand, a certain percentage of these cases either have died or formed a localised abscess. Waiting for an abscess to come to the surface so that it can be opened extra-peritoneally is hazardous, as the risk of a general peritonitis following the efficient drainage of pus across the peritoneum is negligible; some operators are inclined to impose too severe a task upon the peritoneum and to enture without drainage cases from which a definitely suture without drainage cases from which a definitely infected appendix has been removed, and even in some While the where there has been actual gangrene. peritoneum is able in many cases to satisfactorily overcome the infection, results are more often disastrous when there is much pain at the onset, where the temperature or the pulse is high, or where the abdominal rigidity is well-marked and extensive; in fact, in all but those cases in which the objective and subjective signs are absolutely trivial, the sooner an operation is performed the better. It must be remembered, however, he remarked, that the surgeon is not dealing with certainties, but with comparative risks, and an operation is usually the safer plan.

In the present case the patient was anæsthetised, the abdomen opened in the usual manner, a small amount of free fluid mopped up, and an acutely inflamed appendix covered with lymph and bathed in a small quantity of free pus excised. Drainage tubes were passed into the flank, into Douglas's pouch, and down to the stump of the appendix, dressing applied

and the patient returned to bed.

When there is a large amount of free fluid in the abdomen it is better. Mr. Edmunds said, to drain by means of drainage tubes, when the affected area is small; as, for example, when there is a gangrenous hernia buried in the midst of coils of adherent intestine, it is better to leave the wound widely open and to pack it with gauze, care being taken to push the small intestine out of contact with the packing by interposing the colon or omentum as far as possible. Sitting the patient up in bed after the operation is a most excellent plan, but it must be done with careful supervision of the patient's pulse. The majority of supervision of the patient's pulse. The majority of patients, however, stand it perfectly well.

Ten days after operation the patient was making

an uninterrupted recovery.

### TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION.

MEETING HELD MAY 13TH, 1909.

The President, Dr. HERBERT Spencer, in the Chair.

DR. T. W. EDEN read a paper on

THE OPERATIVE TREATMENT OF RUPTURE OF THE UTERUS, WITH AN ACCOUNT OF THREE CASES TREATED BY ABDOMINAL HYSTERECTOMY.

The author summarises the discussion on rupture of the uterus at the Obstetrical Society in 1900, introduced

by Dr. H. R. Spencer, who related four cases treated by gauze-packing, and advocated the use of this method in practically all cases. In 1901 Varnier recorded his experience of uterine rupture, condemned conservative treatment such as gauze-packing, and advocated abdominal section for removal of the uterus in all serious cases.

CASE I.-A case of rupture during version for transverse presentation in a ii.-para, æt. 29, at Charing Cross Hospital, on January 22nd, 1905. Rupture was complete, the placenta having passed into the peritoneal cavity. The placenta was removed by hand, the peritoneal cavity douched through the rent, which was and an attempt made to pack the rent, which was very extensive, with gauze. Fourteen hours after delivery, as there was evidence of fresh internal bleeding, the abdomen was opened, and free bleeding found from the edges of the laceration, which the gauze-packing entirely failed to control. The uterus was re-moved by the supra-vaginal method, the pelvic peri-toneum closed, and the vaginal portion of the rent then packed from below. The patient made a good

recovery.

CASE II.—A case of rupture during version with a vi.-para, æt. 33, at Queen Charlotte's Hospital, on April 10th, 1908. She had previously been twice operated upon, the first time for retroversion, the uterus being ventrofixed; the second time for extrauterine gestation; the pelvis was flat (c.v. 3½), and "pendulous belly" was well marked. The placenta had passed into the peritoneal cavity, and the rent was complete and very extensive. Three hours after delivery the abdomen was opened, and the uterus relivery the abdomen was opened, and the uterus removed by the supra-vaginal operation; vaginal drainage was employed, and the patient made a good

recovery CASE III.—A case of spontaneous rupture during the second stage of labour in a ii.-para, æt. 25, Charing Cross Hospital, January 17th, 1909. After a prolonged first stage, during which the membranes remained unruptured, strong labour pains set in, and the head advanced well into the pelvic cavity. The patient was then violently sick and immediately became collapsed; hæmorrhage occurred from the vagina, and on examination the head was found to have receded and could no longer be felt. Diagnosis of incomplete rupture no longer be felt. into the left broad ligament was made, and the fœtus extracted per vias naturales. A complete and very extensive rupture was then discovered; the pelvis was contracted (c.v. 31 inches). Abdomen opened three hours after delivery; the left ovarian artery was torn and had retracted while still bleeding, beneath the periods above the politic being. Hence we have the politic being the periods and the periods are the periods are the periods and the periods are and had retracted while still bleeding, beneath the peritoneum above the pelvic brim. Uterus removed by the supra-vaginal method, and vaginal drainage employed. The patient at first rallied after the operation, but died rather suddenly 7 hours later. At post-mortem examination fresh bleeding was found to have occurred from a tear of the bladder, which had not been noticed at the operation. at the operation.

In considering the general question, it is pointed out that the three risks associated with this accident are shock, hæmorrhage and sepsis. The author believes that deep bleeding occurs with greater frequency than has been supposed, and may be met with in both complete and incomplete rupture, although the risk is greater in the former. Cases of incomplete rupture have been described in which a large hæmatoma extending from the pelvis to the diaphragm has been found. The hæmorrhage which immediately follows the rupture usually ceases spontaneously, but recurrent bleeding is frequent, because uterine retraction cannot control it, and the bleeding may in part be extra-uterine. To control hæmorrhage is therefore an indication of the first importance.

About 50 per cent. of the mortality of uterine rupture is due to sepsis, the commonest form being acute uterine septicæmia and general peritonitis. The general mortality of uterine rupture at the present time is probably over 70 per cent. Many deaths occur within an hour after delivery, and this must be borne in mind in considering the results of operative treatment.

In estimating the mortality of methods of treatment, only cases occurring in series at lying-in institutions and treated by reputed observers have been considered. The mortality of expectant treatment is estimated by von Walla at 60 per cent.; by Kolomenkici at 61 per cent.; by Lobenstein at 92 per cent.; and by Munro Kerr at 90 per cent. Nothing like the good results from packing cited at the discussion in 1900 have been obtained by other observers. Thus Lobenstein has recorded 14 cases thus treated with a mortality of 92 per cent.; Draghiesco and Cristeanu record 6 cases, with 5 deaths; Klein has collated from various sources 65 cases, with a mortality of 52 per cent. In the author's opinion expectant treatment is only suitable for cases of incomplete rupture of moderate severity. In all severe cases, whether complete or incomplete, operation gives the patient the best chance of recovery.

Cases of extensive incomplete rupture may be quite as serious as those of complete rupture, and are attended by exactly the same risks. Abdominal section and removal of the uterus by the most rapid method possible is recommended because: (1) it is the only certain way of controlling hæmorrhage; (2) the uterus has frequently been infected previous to the operation; (3) if the uterus is left and the patient recovers, the risk of repeated rupture in a subsequent pregnancy is high. The mortality of this operation in skilled hands at the present time is estimated by Kolomenkici at 36.3 per cent., and by Klein (cases since 1890 only) at 37.5 per cent, thus comparing very favourably with the results of expectant treatment as estimated by the same observers. The importance of vaginal drainage is insisted upon.

Laparotomy and suture of the rent has been shown to yield a higher mortality than hysterectomy, and, for the other reasons stated, is not to be recommended.

In cases of extreme urgency it may be wiser, after opening the abdomen to control hæmorrhage, simply to pack the rent from above into the vagina, and remove the uterus a day or two later by the vaginal

Vaginal hysterectomy has not received an extensive trial. The objection to it is that it does not allow of that complete exposure of the field of injury which is required, and bleeding vessels may escape notice when operating by the vaginal route.

Dr. LIONEL SMITH read a paper on RUPTURE OF THE UTERUS.

A series of ten cases of complete rupture of the uterus, eight of which were treated in the General Lying in Hospital, and are the total number of

examples of this accident which have occurred among 10,989 deliveries during the last twenty years.

Case I.—Patient, æt. 24, iii.-para. Labour occurred at term; vertex presentation; craniotomy. Duration of labour, four hours. Rupture of lower segment of the uterus. Treatment: Stimulation. Result: Rethe uterus. Treatment: Stimulation. Result: Recovery. Subsequent labour nineteen months later; vertex presentation; forceps delivery on account of excessive violence of the pains. Duration of labour,

CASE II.—Patient, æt. 26, a primigravida. Cbstruction of labour due to contraction of the pelvis; vertex presentation. Duration of labour about five days; cephalotripsy. Rupture of the lower segment of the uterus. Treatment: The rent in the uterus was lightly packed with gauze. Result: Death in seven hours.

CASE III.—Patient, æt. 37, v.-para. Labour at term;

obstructed delivery due to contraction of the pelvis; vertex presentation. Rupture of the lower segment of the uterus, and escape of the fœtus into the peritoneal cavity. Treatment: Laparotomy, suture of the rent in the uterus, gauze drain per vaginam. Result:

Death in 2½ hours.

CASE IV.—Patient, et. 33, a primigravida. Labour at term; transverse lie; tonic contraction of the uterus; decapitation and cephalotripsy. Small rent in the lower segment of the uterus, extending upwards from a laceration in the cervix. Result: Death in 20

hours from peritonitis.

CASE V.—Patient, æt. 31, ii.-para. Labour at term; transverse lie; obstruction due to contraction of the pelvis; version and cephalotripsy. The placenta passed into the peritoneal cavity through a rent in the lower segment of the uterus. Duration of labour, 26 hours. Treatment: Stimulation. Result: Death in six hours.

CASE VI.—Patient, æt. 26, iii.-para. Obstructed labour due to hydrocephalus; cephalotripsy. Rupture of lower segment of the uterus. Duration of labour, 50 hours. Treatment: Stimulation. Result: Death in 12 hours.

CASE VII.—Patient, æt. 37, viii.-para. Twin labour, second child transverse. Duration of labour, 18 hours. Rupture of the uterus and escape of the fœtus and placenta into the peritoneal cavity. Result: Death immediately after the patient was admitted to the hospital.

CASE VIII.—Patient, æt. 40, x.-pate. term; vertex presentation; sudden and violent pains; forcens delivery. Result:

Death ten minutes after delivery.

CASE IX.—Patient, æt. 39, ix.-para. Labour at term; breech presentation; delay with after coming head. Large rent in the lower segment, small rupture and several fissures in the muscular substance of the upper segment; hæmorrhage into the peritoneal cavity. Result: Death immediately after delivery.

CASE X.—Patient, a multipara xi. Labour at term; breech presentation; obstruction due to cancer of the cervix; perforation of the after-coming head. Result: Death 11 hours after delivery.

Eighty per cent. of the patients were multiparæ, 20 per cent. primigravidæ. The cases are divided into two classes. In the first class the rupture was due to an abnormal excitability of the uterus, resulting in a great increase in the strength and frequency of the contractions together with a premature retraction, a condition exactly similar to that produced by the administration of ergot.

In the second class the rupture followed a prolonged and obstructed labour, and in some cases was possibly the result of perforation with an instrument, or was

due to some intra-uterine manipulation.

The symptoms presented by the various cases were shortly discussed.

The President (Dr. HERBERT SPENCER) said that, in considering the question of treatment, it was to be borne in mind that, although rupture sometimes occurred spontaneously and in careful hands, it arose for the most part in bad and dirty midwifery practice, and consequently the tissues were often bruised and infected, and many would die, however they were treated. He showed ten specimens of rupture from the museum of University College Hospital. In two of the cases abdominal hysterectomy had been performed, with a fatal result in each case from shock. Only one of the ten cases was a suitable case for supravaginal hysterectomy. Total hysterectomy was indicated in those cases which required the removal of the uterus, but in his opinion these patients were usually too much shocked to stand removal of the uterus by the abdominal route. He thought there should be no difficulty in controlling hæmorrhage after vaginal hysterectomy. He did not think Dr. Eden had made out a case for abdominal supra-vaginal hysterectomy as a routine method of treatment in com-plete cases of rupture of the uterus, and still less for

cases in which the peritoneum was not involved.

Dr. Hubert Roberts related four cases of rupture of the uterus which had come under his care. first of these was treated by plugging the rent, and she recovered. In the second and third cases the abdomen was opened and the rent sewn up with silkworm-gut sutures. One of these recovered, and three years later was safely delivered of a full term child at Queen Charlotte's Hospital. The fourth case died very soon after delivery, before it was possible to attempt any treatment. As to treatment, Dr. Roberts thought no hard and fast rule could be adopted. Packing might be advised in those cases where the rupture was incomplete, or the patient's condition so grave that abdominal section was out of the question. In other cases he thought the abdomen should be opened, but was of opinion that closure of the rent by sutures with drainage by gauze into the vagina would

yield equally good results as removal of the uterus.

Dr. Drummond Robinson stated that he had five cases of ruptured uterus under his care. One patient died shortly after rupture had occurred. In two cases the rupture was discovered after the delivery of the child. In both of these cases gauze-packing was employed, and they both recovered. In two other cases the fœtus was still in the uterus when the rupture was discovered, and abdominal hysterectomy was performed. Both patients died. The speaker was surprised that others had not alluded to this class of rupture in which the fœtus is still in the uterus, and delivery by the vagina is contra-indicated. He thought that in cases of this kind there was no option but to perform abdominal section and at the same time to remove the uterus.

Dr. J. S. Farebairn said he could speak only from a small experience of about six cases, in which, however, the three methods of plugging, suture of the rent, and abdominal hysterectomy had been tried. He thought that there was a place for all these forms of treatment, and that what should be aimed at was some means of recognising the cases suitable for each method. He had had three cases in which no operative treatment was done, two of which made as straightforward a recovery as any uncomplicated labour case. In one of them there was a rent through the posterior wall of the uterus which admitted three fingers, but there was no bleeding and a gauze plug was all that was required to prevent intestinal prolapse. In another case there was an extensive laceration into the left broad ligament, large enough to admit the whole hand, but not communicating with the peritoneal cavity. Nothing at all was done, and she made an uninterrupted recovery. A third case in which plugging was tried died in 24 hours. In the case in which hysterectomy was done, the child, which had been lying transversely, had escaped into the left broad ligament, and the placenta had been extended into the peritoneal cavity. Both child and placenta had been delivered by the outside practitioner before the patient was admitted. She was suffering profoundly from shock and was bleeding, so the abdomen was opened. The posterior layer of the broad ligament was torn into shreds, the ureter remaining as a bridge, and the uterine rent was so ragged that no other course than hysterectomy was practicable. This patient died a few hours later, as also did one mentioned by Dr. Lionel Smith, in whom partial suture of the rent and drainage was tried. These few cases exhibited such differences in symptoms that no one form of treatment would have been suitable in all.

Dr. EDEN and Dr. LIONEL SMITH replied.

### ROYAL ACADEMY OF MEDICINE IN IRELAND

SECTION OF STATE MEDICINE.

MEETING HELD APRIL 30TH, 1909.

The President, Dr. W. R. Dawson, in the Chair.

<del>\_\_\_\_</del>

PHYSICAL DETERIORATION AND A REMEDY. MR. J. B. STORY read a paper on the above subject. He remarked that there are no means of ascertaining with perfect certainty whether our population is physically degenerating or not. No statistics are available in the United Kingdom on this point. But it is known that urbanisation is increasing, and plenty of evidence exists to show that this tends to physical degeneracy. In support of this German statistics were quoted. Attention was called to the reports of three Parliamentary Commissions—(1) Inter-departmental on Physical Degeneration (1894); (2) A Royal Commission, Physical Training, Scotland (1903); and (3) Poorlaw Commission, whose report has been published this year. The first recommends a permanent anthropometric survey of all children and young persons, methodical physical instruction in all schools, and compulsory drill and physical exercises for all growing lads. The second makes almost identical recommendations, and the third, in a majority report, states that the most effective and thorough method of infusing into boys approaching adolescence a sense of discipline and self-restraint, both physical and moral, and of improving their physique for subsequent industrial occupations would be a universal system of a short period of military training. The author commented upon the utter lack of any systematic physical educa-

tion in Irish schools, and made the following recommendations, which were afterwards adopted by the meeting:—

(1) That a permanent anthropometric survey should

be made of children and young persons.

(2) That physical drill should be compulsory, in conjunction with a proper system of medical inspection, in all schools primary and secondary.

(3) That all boys between the ages of fourteen and eighteen, who are physically fit, should be compelled to belong to Boys' Brigades or Cadet Corps, or to attend classes where physical drill of a military character is conducted.

(4) That all youths at age of eighteen (rich and poor), who are physically fit, should be compelled to undergo

a period of military training.

Dr. FALKINER spoke from personal experience of the value attaching to boy-scouting. Apart from the question of a territorial army, military training would be in every way an advantage. He thought, however, that it was a good thing to let a boy feel some sense of responsibility at an early age, as he believed it led to the making of better men.

Professor M'WEENEY said he became convinced of

Professor M'Weeney said he became convinced of the great utility of compulsory military training when living in Germany. The habits of co-ordinated action, subordination and devotion to duty, and sacrifice of self, which a well-conducted course of military training conduced, are invaluable in the development of the individual and the nation. The lack of co-ordination was very marked in this country, and far too many of the children of the poorer classes were allowed to wander about the streets to acquire an anti-social character of mind, and to feel themselves as outside the scheme of things. The German system impressed him with the feeling of solidarity, and he considered the recommendations made by Mr. Story as most essential to the well-being of the State.

Surgeon-General BOURKE spoke of his experience of military training. There was a great difference between squads that had only a few days' service and those that had longer periods. He could assure them that even three months made a decided improvement, and the Swedish system had been found to be of great advantage. He had recruited at Preston and had rejected over half, but in agricultural districts, although the men had not the same intelligence, they were physically fitter. For scouting the town men would be much sharper.

Dr. M'VITTIE thought that the teeth were, perhaps, the most important indication of degeneration. He could not see how a man was going to stand hard work if he had not good opposing molars. It had been shown that 86 per cent. of the children in schools in Great Britain had very bad teeth, and he thought the figure showed that the race was degenerating at a rapid pace. If there was to be more prolonged physical drill, it should be under the control of the medical profession. If carried out under the control of those who knew something about the machinery of the body, it might be a great blessing. He was satisfied that well-handled compulsory service would benefit the country, not only physically, but mentally and morally, and do away with the reproach of the policeman all over the place, but there was a danger of letting the matter be rushed by enthusiastic but ignorant persons.

Dr. Nolan spoke of the good results of the Swedish

system in his asylum in Downpatrick.

The PRESIDENT said he had been converted to the doctrine of compulsory military service by a residence in Germany. The average young German, previous to the age of military service, was a slouching, round-shouldered person, but afterwards was well set up, vigorous, and manly looking. It had been argued against compulsory military service that it took the male population from their occupations when they should be learning them, and retarded the development of the country, but he thought the progress of Germany did away with that argument. The great advantage of early training was that it got a boy at the stage when he combined the self-indulgence of the child with some of the force of a man. It was a critical stage, and drill would be the salvation of the young men of the

Mr. STORY replied.

GENERAL ANÆSTHETICS BILL.

Dr. KIRKPATRICK read a paper dealing with the General Anæsthetics Bill now before Parliament. paper discussed the events which have forced this matter recently on the public attention, and also showed the efforts which have been made in former times to check the mortality from anæsthetics. Dealing with the present Bill, the writer opposed the proposed exclusion of dentists from the ranks of the anæsthetists. This opposition was based on the high position of the dental profession, its past record in connection with the administration of anæsthetics, as well as on the curriculum at present enforced on its students. The onus of proof that the safety of the public demands this exclusion lies with those who would enforce this exclusion, but so far it would appear that this proof is not forthcoming. In the writer's opinion, the course of instruction laid down for dental students of the Royal College of Surgeons in Ireland is quite sufficient to permit the dentists of the future to be entrusted, with perfect safety to the public, with the important duty of administering anæsthetics.

Dr. CRAIG said that Dr. Kirkpatrick stood almost alone in his defence of the dentists who were not also registered medical practitioners. Although in favour of the Bill, he thought they might legislate in far too many directions, and so overload the student. The dentist who had taken the trouble to become a qualified medical man would not be touched by the Bill. only those who had not taken the trouble to go through the ordinary medical curriculum who would be hardly

hit, and rightly so, in his opinion.
Dr. Kirkpatrick, in reply, said he did not think the privilege of administering gas should be taken away from the dentists without due cause being shown, and the onus of proof lay with those who wished to with-draw the privilege. That was a point which had been lost sight of in discussions on the subject.

### CORRESPONDENCE.

### FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.
Paris, May 23rd, 1909. THE DEPOPULATION PROBLEM. PROF. COURMONT, of Lyons, has recently sounded a note of alarm on the subject of the depopulation in

France.

France.

Hitherto, he says, France held the first place amongst the European nations. Political changes and wars reversed the position. After the war of 1870 France fell behind Germany. Germany had 41 millions inhabitants, France 36, then came Austria-Hungary with 35, England with 31, Italy with 26. In 1907, or 38 years afterwards, France had fallen to the fifth rank in Europe. Russia leads; Germany has advanced to 61 millions (gain, 20 millions); Austria to 48 millions (gain, 13 millions); England to 44 millions (gain, 13 millions). The population of France rose to 39 millions (gain, 3 millions only), while Italy has gained in the same period 7 millions (26 to 33 millions). (26 to 33 millions).

The annual increase per 1,000 inhabitants for the above countries renders more clear the facts. During one decade (1896-1906) the increase for Germany was one decade (1896-1906) the increase for Germany was 15.2; Austria-Hungary, 13.2; England, 11.8; Italy, 10.8; France, 1.5. In other words, each year one thousand Germans became 1,015.2; a thousand Austrians became 1,013.2; a thousand English 1,011.8; a thousand Italians, 1,010.8; while a thousand French became but 1,000.5. It is easy to calculate consequently in how many years Germany will have twice the population of France, and in how many years Italy will have outstripped France. Will this state of things improve? According to Prof. Courmont it will become rather worse. it will become rather worse.

Not only is the French gain slight, but it is too often transformed into a deficit. In certain years during the last decade, the number of deaths exceeded that of births. Such a fact is without precedent in the world during periods of peace and in the absence of grave epidemics. If energetic measures are not taken this will become the rule in France, and slowly but surely the life of the nation will go out. With regard to the effective population of the 86 departments into which France is divided, more than the half (44) presented in 1905 a decrease in the population; five (North of France) showed an increase of 3,000 individuals, while the remainder were stationary.

A remedy to such a situation is imperative, and this remedy Prof. Courmont believes it possible to find in hygiene. The factors of a problem are intimately connected with the research of the cause, and in order to find a solution to this problem, each of the factors must be studied separately

of the factors must be studied separately.

In the question of depopulation, the causes may be limited to two: natality and mortality. A country becomes depopulated either because it produces few children or because it loses too many. The movement of the population is the result of a balance between the receipts (births) and expenses (deaths).

NATALITY. French natality is the lowest in Europe and in the whole world! In Germany it is 33, in Italy 31, in England 26, and only 19 in France. But in this respect it may be said that the number of births diminishes everywhere. Since 1870, it fell from 35 to 33 in Germany, from 36 to 37 in Italy, from 35 to 26 in England, and from 25 to 19 in France. It is even in England that the birth-rate has, proportionally the most diminished

ally, the most diminished.

The causes of this diminishing natality are regulated by laws well-known to economists: degree of civilisation, expense of living, multiplication of needs, education, etc. Such are the general causes against which there is but little hope of reaction. It is, however, an acknowledged fact that restriction of natality is voluntary: a country has the number of children it wishes for; it is not a question of race, morality, marriage, divorce, etc.; it is a social and economical question, difficult to solve.

MORTALITY.

The mortality for France is 20 per cent. like that of Italy. Certain countries as Russia and Austria-Hungary have a much higher mortality, but Germanv (48 per cent.), England (15 per cent.), and above all the Scandinavian countries have a much lower mortality. Prof. Courmont is convinced that better sanitary conditions similar to those existing in England and Germany would considerably lessen the mortality in France, and procure some 300,000 individuals per year for the country. Many diseases are avoidable if proper prophylactic measures are taken. In France the three great causes of mortality are: Infantile mortality, tuberculosis, and alcoholism. Nothing has been done against tuberculosis, yet 100,000 deaths might be prevented. Alcoholism and especially absinthism are consuming the very vitals Infant mortality in Norway is of the population. 69.4 per 1,000 children, while in France it is 150. Thus 64,480 infants are annually sacrificed. By way of conclusion Prof. Courmont says that if it is imperative that the public bodies should adopt measures of sanitary reform against the threatening danger, it is also necessary that the French mentality should undergo a transformation. In France it is considered the proper thing to cover hygiene and sanitary reformers with ridicule; and doctors are the first to disobey the law by not notifying contagious diseases. The slightest ennui is intolerable, altruism is but a meaningless word, and selfishness governs the unfortunate country.

In order to understand the painful situation, it is necessary to travel, and especially to visit the northern countries. There all is discipline, faith in progress, in science; the general interest is the great social law. As soon as a measure, no matter how vexatory, appears necessary for the common good, every one submits. Questions asked as to the difficulty of establishing compulsory vaccination, or notification of contagious maladies are not even understood. The answer is: "But since it is the law!" Happy country!

In France, the word Liberté written on the public monuments is not understood. Absolute liberty cannot exist, there are only liberties: liberty to believe, to think, to vote, to write, is certainly sacred; but no liberty should be claimed to injure the neighbour, to disobey the laws, to let insalubrious dwellings, to sell absinthe, to refuse vaccination, or notify contagious maladies. Such liberty should not be tolerated.

Social sanitation is not comptatible with absolute liberty, it exacts a very clear comprehension of responsibilities and duties towards our neighbour; it is altruistic.

### GERMANY.

Berlin, May 23rd, 1909.

TRANSPLANTATION OF THE KIDNEY. At the Medizinische Gesellschaft, Hr. Unger discussed this subject. He first mentioned the earlier attempts to transplant the kidney, which always failed, until Carril introduced his method, which consisted in this: that he removed both kidneys along with a portion of the aorta and vena cava, the ureters and the bladder from one animal and transplanted them into another. The speaker had repeated the experiment. He explained the method to the Society by the aid of drawings. The chief difficulty of the operation, which with practice could be performed in from 50 minutes to an hour, consisted in the suture of the vessels which were only small in the animals experimented on. He had performed the operation 70 times. At first most of the animals died during the first few days either from narcosis or from uraemia, but the results gradually became better. Hæmorrhage was observed gradually became better. Hæmorrhage was observed on two occasions; several died from peritonitis. One bitch which survived the operation 18 days was not uræmic, but died of diarrhea; on examination after death a thrombus was found in the vena cava below the suture and an aneurysm at the site of the suture. A cat retained her own kidneys in addition to the transplanted ones, and lived four weeks; when her own proper kidneys were then extirpated she died of uræmia. In many similar cases it was seen that when the proper kidneys were at first left in, the microscopical changes in the transplanted kidneys were greater than when they were extirpated at once.

The speaker concluded that the experiments showed that kidneys removed from one animal and implanted into another continued to act, and that the disturbance of the circulation caused by the operation gradually

Hr. Benda had examined several of the kidneys removed, and found in them infarcts and hæmorrhages, but the tissues were undoubtedly well retained, both in the glomeruli and in the canaliculi.

Hr. Katzenstein made a report on experiments he

Hr. Katzenstein made a report on experiments he had made regarding the establishment of a collateral circulation in the kidneys.

He displaced the kidney outwardly, so as to stretch the renal artery and narrow its calibre, and thereby make the circulation more difficult. This was necessary, as the blood always went the nearest way, and the development of collaterals did not take place. He then fixed the kidney between the abdominal muscles, and six weeks later divided the renal artery. The kidney now acted smoothly, and the injection passed from the aorta, in spite of the ligature of the renal artery.

artery.

Hr. Zondek said he had performed similar experiments, but without success.

At the meeting of May 5th, Hr. Hartog related a case of

PUERPERAL PYÆMIA WITH RECOVERY AFTER TREN-DELENBURG'S OPERATION.

A woman aborted at the sixth month of pregnancy with symptoms of high fever. The fever continued after the abortion, with fætid discharges from the vagina, and numerous injections of Aronsonn's serum had not dissipated it. The speaker saw the patient a month after the abortion. There were then rigors, a pulse of 120 to 130, the temperature rose to 40° C., and the general condition was bad. Considering that the case was one of undoubted pyæmia, he proposed Trendelenburg's operation, which, after some hesitation, the patient agreed to. At the laparotomy the broad ligament was found to be occupied by large

thick veins; double ligature of the hypogastric veins of both sides, ligature of the spermatic vein. The success of the operation was surprising; the next day the temperature had fallen to 38° C., and after that did not go above 37° C. After a favourable re-convalescence, the patient got up three and a half weeks after the operation, and continued her occupation as a midwife. The danger of the operative proceeding was but slight. A fatal termination followed on advance of the thrombus to the vena cava; operation, therefore, should not be too long delayed.

# AUSTRIA. Vienna, May 23rd, 1909.

At the "Gesellschaft der Aerzte," Nobl showed a patient, æt. 67, with a papular eruption on the arms, axilla, dorsum of penis, scrotum and lower limbs, ranging in size from a needle point to a hemp seed. They had a polygonal shape, a mother-of-pearl shimmer, steel blue colour with an erythematous base slightly elevated and irregular in contour, but when met with aggregated they were more ovoid and serpiginous. Whatever may have been the cause, the dominant opinion was a mechanical origin. This wos more prominently demonstrated in the palms of the hands and fingers, where the papules appeared like large shot covered with a horny lamella having a violet shiny colour. These patches would cover the area of a five-shilling piece.

In support of the traumatic origin a similar appearance, though seldom associated with it, was present on the mucous membrane of the mouth; on the upper and lower lips, angles of the mouth, and below the tongue these changes were present. None of the so-called lichen genisis was present as far as toxico-dermia was concerned, but the mechanical irritative cause recognised by Pospelow was incontrovertibly present.

PASTEUR'S DISEASE.

Beer, at the "Gesellschaft für Innere Medizin," raised the question of a new disease which was similar to many of the other subcutaneous changes, but of a more intense nervous change, which has led to the term hysterical being applied. The pain is usually confined to a narrow area located in the fibrous tissue, and resisting all treatment. It is sometimes accompanied with peculiar streaks on the cutaneous surface of a roseate or violet hue, with vascular dilatation. This peculiar diseased centre lies deep, but, with careful probing, the exact spot can be determined. Hitherto this disease had had no name, but, occurring in young pople, and the female sex as a rule, it has been classed under the head of hysteria, which is certainly a misnomer. The male sex is not exempted from the disease associated with the vascular ectasia, as may be often seen along the ribs of the drinker, but we find it not infrequently in the total abstainer also, accompanied with great pain. The principal sites are the hip, shoulders, back and chest walls.

A second form of this fibrous tissue disease is found

A second form of this fibrous tissue disease is found with no visible cutaneous phenomena, narrowly circumscribed with neuralgic pain above the pubis. The pain is the guide to cicatrix-like firmness in the deep fibrous tissue in the fascia near the sheath of the rectus muscle. A deep retraction about the size of a pea or a "heller" may be found, very painful, but movable from side to side. This pain is often out of all proportion to the observed lesion, not uncommonly associated with colic pains, which leads the attendant to the suspicion of gall-stone, peritoneal strangulation, etc., or to the diagnosis of neurosis, neuralgia, or some pressure on an abdominal nerve.

Whatever may be the cause of this deformity in the fibrous tissue, it is capable of promoting general rigidity of the locomotor apparatus, which was described by Larey and Percy about the beginning of the last century as extending to all the joints of the body, even to an ankylosis of the jaws.

Pasteur, in London, 1896, seems to have isolated the disease in his description of a young woman with spinal rigidity and apparent ankylosis of the distal joints of the limbs, including the knees and the elbows.

This fixation was not due to any disease of the joints, but some periarticular changes in the soft tissues, which is more rare than the rigid form of the spinal cord. From the sclerodermic combination, the rigidity of the spinal cord is more frequent than the fixation form, which led Pierre Marie to affirm that it was a disease of the articulations of the spine and large joints. It is important to know that this rigidity of the spine, combined with shoulder and hip joints, have no disease to be recorded, but the periarticular soft parts have been found changed, but curable.

# FROM OUR SPECIAL CORRESPONDENTS AT HOME.

### SCOTLAND.

THE LATE DR. W. W. IRELAND.—There passed away suddenly, on the 17th inst., at his home in Musselburgh, Dr. W. W. Ireland, well-known by his work on imbecility and mental defect. Dr. Ireland, who was in his 77th year, was a veteran of the Indian Mutiny. He was an assistant surgeon attached to the Bengal Horse Artillery, and received his baptism of fire at the siege of Delhi, where he was dangeroulsy wounded and lost an eye. After a long and tedious conva-lescence, he returned to Scotland, and devoted himself to the study of mental diseases. He was a man of unusual culture and breadth of mind, an accomplished linguist, and a scholar, as his numerous contributions to psychology and other paths on the borderland of medicine testify. He was a corresponding member of the Psychiatric Society of St. Petersburg, and of the Medico-Legal Society of New York, and was a diligent frequenter of various foreign and international psychiatric congresses. His principal work, "On Idiocy and Imbecility," appeared in 1877, and in 1898 a further volume, "The Mental Affections of Children: Idiocy, Imbecility, and Insanity," was published. Idiocy, Imbecility, and Insanity," was published. Until quite recent years Dr Ireland's work continued to be almost the only text-book in the English language on the product of the control of the contr guage on the particular subject, and though it now has authority. Among other well-known books, "The Blot on the Brain" (1885) and "Through the Ivory Gate" (1889), may be specially referred to. They are studies in heredity and psychology, and are illustrated with a great wealth of historical example. Dr. Ireland was at one time Medical Superintendent of the Larbert Institution for Imbeciles, and of Miss Mary Murray's Institution for Girls at Prestonpans. Dr. Ireland continued to take a keen interest in medical work until the last days of his life. Only a few years ago he read at the Edinburgh Medico-Chirurgical Society a paper on the alleged increase of insanity in Scotland, in which he concluded that the increase was largely a matter of statistics. He was a regular attender of the Morison lectures and other meetings connected with his speciality. In 1905, the jubilee of his entry into the medical profession, a number of his friends presented him with a purse of sovereigns, and it was characteristic of the man that he resolved to devote part of this money to the publication of an historical work on which he had for some time been engaged. Dr. Ireland was greatly and deservedly respected by those who knew him. He was a hospitable, kindly gentleman, a man of upright character and quite exceptional attain-ments. Dr. Ireland is survived by a son and daughter, the former being a member of his father's profession.

THE LATE DR. KENNEDY, EDINBURGH.—On the day of Dr. Ireland's death, a large circle of patients and friends were shocked by learning that Dr. Charles Kennedy expired with tragic suddenness. He appeared to be in his usual health on Sunday, and left the house shortly after midnight with the intention of visiting a patient, but only got a step or two from his front door when he died from sudden heart failure. Dr. Kennedy was about fifty years of age, and was a son of the late Mr. David Kennedy, the well-known Scottish vocalist, from whom he inherited many of the musical qualities which distinguished the family. He graduated M.B., C.M., in 1881, and four years later was awarded a gold medal for his M.D. thesis. He had a large

practice in Edinburgh, and was an enthusiastic Freemason. His vocal talents brought him much into request on all social occasions, and he was a popular member of the Pen and Pencil Club. He is survived by a widow and three children, one of whom is studying medicine.

PRINCIPALSHIP OF ABERDEEN UNIVERSITY .- Amongst other names spoken of in connection with the appointment of a successor to the late Principal Marshall Lang are those of Professor George Adam Smith (Glasgow), Professor Matthew Hay (Aberdeen), and Professor Sir W. Mitchell Ramsay. The appointment rests with the Crown. Local feeling appears to favour

the selection of Professor Matthew Hay.

EDINBURGH PARISH COUNCIL AND THE ROYAL INFIRMARY.—At a meeting of the Council held on May 17th, the question of the treatment of cases of temporary mental disease in the Royal Infirmary was under discussion. The sub-committee which has been dealing with the matter (which arises out of an application by the Infirmary for a contribution from the Council's funds), reported (1) that the poor of the parish receive such benefit from the Infirmary as warrants the Council's favourable consideration of the managers' application for a grant; (2) that a contribution of £150 a year be made; (3) that a payment of 3s. 6d. per diem be made to the Infirmary for each case of temporary mental disorder sent to that institution by the Inspector of Poor. The report was adopted tentatively for a period of one year.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.-

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—
FELLOWSHIPS.—At a meeting of the College, held on
the 19th inst., the following gentlemen were elected
Fellows:—James Malcolm Christie, M.B., Ch.B., Edinburgh; John Gilmour, M.B., Ch.B., Edinburgh;
Ralph Tennyson Jupp, M.B., Ch.B., Ilford; Angus
Dugald Macintyre, M.D., C.M., Canada; John
Stevenson Mitchell, M.B., Ch.B., Dunfermline;
George Raffan, M.B., Ch.B., Edinburgh; Henry
Speirs, M.D., Gavinton, Duns; Cyril Hocken Tewsley,
M.B., Ch.B., Bradford; and Reginald William
Townley, L.R.C.S.E., Portobello.

AWARDS.—The bronze medal and microscope pre-

AWARDS.—The bronze medal and microscope presented to the Royal College of Surgeons, Edinburgh, by Colonel William Lorimer Bathgate, in memory of his late father, William McPhune Bathgate, F.R.C.S.E., Lecturer on Materia Medica in the Extra Academical School, was awarded, after the usual competitive written examination in Materia Medica, etc., held for the Session 1908-1909, to Miss Marion Macintyre, of Edinburgh; and the first annual award of the Ivison Macadam Memorial Prize in Chemistry. consisting of a bronze medal and case of instruments, was, after a competitive written examination in Chemistry, held for Session 1908-1909, made to Mr. Charles Henry Kemball, of Edinburgh.

# LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

MEDICAL LAW REFORM.

To the Editor of The Medical Press and Circular.

SIR,—In your Editorial Note to-day on the recent dental prosecutions, you remark that "the day of the quack dentist seems drawing to a close, and, like the unqualified medical assistant, he will probably disappear from the scene." It will be surely the fault of the profession if not only the unqualified assistant, but the unqualified and fraudulent pretender, does not also disappear from the scene. It is impossible to believe that reform could be delayed for a day if the Legislature was once made clearly to understand the present scandalous condition of medical law. has been done for dental and veterinary surgery can be done for the medical profession. The letter of "An Obscure Practitioner" puts the case admirably. The movement towards the appointment of a Royal Commission is, I am glad to say, advancing. The Council of the British Medical Association, and the General Medical Council, have both taken the matter up, and it has been brought before the Privy Council. Out of

this has arisen action by the Local Government Board. The Board has issued a circular to Medical Officers of Health asking for information with regard to unqualified practice in their districts. Unfortunately the several Councils have not included the traffic in quack medicines and apparatus within the scope of the promedicines and apparatus within the scope of the proposed Commission. Great part of fraudulent practice is carried on under the cloak of that traffic, and if this be not included in the inquiry, any legislation based upon the Commission must prove largely futile. I am striving to draw attention to this fact. I hope you may feel disposed to help me

I am, Sir, yours truly, HENRY SEWILL

May 19th, 1909.

# THE CAMPAIGN AGAINST UNQUALIFIED DENTISTS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—It is to be hoped, now that some of the unqualified dentists have been convicted and fined, that the campaign will extend to all unqualified pretenders the capacity of -- the cancer curer, the bone setter, etc., etc. gentry cannot even put forward the excuse the make-believe dentists can—viz., "living from hand to mouth," and if the heavy fines inflicted have been paid, it would go far to disprove the excuse, but will probably make all offenders look "down in the mouth in future. Without attempting to excuse unqualified dentistry, I may say I have seen better work in the way of dentures produced and fitted by such, when three times the amount had been paid previously by waters to qualified dentists, who, on finding no comfort, sought with success the services of the unqualified man. I feel sure I can be supported in this statement by other medical men, and the question may be asked: Who really does most of the work for the curlified dentist? qualified dentist?

I am, Sir, yours truly,

ALEXANDER DUKE.

# THE MEDICAL LIBRARY ASSOCIATION. To the Editor of THE MEDICAL PRESS AND CIRCULAR.

Sir,-In connection with the first meeting of the Medical Library Association, to be held in Queen's College, Belfast, during the last week in July, a loan exhibition will be held illustrating medical libraries and medical literature. Amongst other things, we are and medical literature. Amongst other things, we ever particularly anxious to receive the following:—(1) MSS, and early printed books. (2) First editions of noteworthy books. (3) Early Irish printed books (there are few, if any, before 1700). (4) Books on tuberculosis. (5) Books upon Celtic medicine. (6) Photographs of libraries. (7) Statistical diagrams giving number of volumes issues readers income atc giving number of volumes, issues, readers, income, etc. (8) Library papers, rules, etc.
The Association will insure all loans, and the

exhibits will be most carefully guarded.

We venture to hope for early and favourable replies, as the time for the preparation of the exhibit is rather short.

We are, Sir, yours truly J. WALKER HALL, CUTHBERT E. A. CLAYTON, The University, Manchester, May 19th, 1909.

# LOCAL GOVERNMENT REFORM.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

Sir,-On more than one occasion, when writing in your valuable paper on the question of sanitary administration, and the positions of medical officers under the Poor-law and under Public Health Acts, I have pointed out that mal-administration and neglect of necessary laws in both departments are mainly due to the inferiority of the local authorities. These authorities are in most places largely composed of, or dominated by, ignorant and vulgar men, who when they have the capacity to understand the importance of their duties, too often allow the furtherance of their own sordid interests to stand in the way of performance of them. This state of things is (as I have also

explained) due to the apathy of responsible classes of the public who decline to take any interest or part in local affairs. The intellectually better part of cracy shirks its duty. I have often urged that local government might be made more efficient in every way if the machinery were largely converted into a bureaucracy. In this the example of Germany might be followed The public should have the assurance, as they have in Germany, that the Government were acting nave in Germany, that the Government were acting upon the best scientific advice, and the orders of the central body might then be carried out. It is interesting to note that Mr. John Burns, in a speech on May 15th, takes up a similar position. Speaking of the need for speedy action in the matter of Poor-law reform, Mr. Burns argued that the best way would be to give a free hand to the President of the Local Government Board, only stipulating that he should report on what he had done every three months to Parliament, so that sanction should be given for each instalment of administrative reorganisation. Mr. Burns is a Radical of Radicals, a Democrat of Democrats, and yet he suggests it as his conviction that it is in some directions less beneficial for the people to govern themselves than to entrust their interests to the control of a well-advised Government department. Most medical officials who have had sufficient experience of our present democratic system will, I think, feel disposed to agree with Mr. Burns.

I am, Sir, yours truly,

M. O. H.

May 17th, 1909.

# AMERICAN BAKED BEANS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,-In your "Notices to Correspondents" last week, mention was made of haricot beans, and American baked beans were mentioned as a wholesome and palatable article of diet. Until a few years ago, American "canned" beans could be got without being wired with the state of the sta mixed with tomatoes, but of late this has not been possible, at any rate as regards myself. Not being able to get them in their unmixed state, I was glad when a lady resident in America, on a visit to this country, instructed me in the American way of cooking beans. The method is as follows:—Allow a pint of beans to simmer three hours, then pour off the water, and place in a baking pan along with a small piece of salt pork or mild-cured bacon, and place on top a good dessertspoonful of syrup, put in just enough water to cover all. Bake until the top part is brown, then stir all up thoroughly, and put back into the oven, until the top is again brown; stir up again. and put into the oven again, continuing this until the whole is a uniform brown throughout. The beans are then ready for serving. With fried ham or any white meat they are a really palatable form of vegetable. Even when cold they are very good to form the substantial part of a salad.

I am, Sir, yours truly,

I. E. B.

# THE VIRULENCE OF INFECTIOUS DISEASE. To the Editor of THE MEDICAL PRESS AND CIRCULAR.

Sir,-The April number of Janus contains an article to which I should like to call the attention of physicians and historians. I offer no comment on the views put forward, but as they may influence medical practice, as well as throw light upon history, medical men throughout the world would do well to consider

The writer, Dr. Otto Effertz, a Governmental vaccinator in Mexico, attempts to prove that the virulence of an infectious disease is not absolute, but relative, being the resultant of two factors, varying according to the country in which the disease is endemic and the to the country in which the disease is endemic and the people who are attacked by it. These factors are:—

(1) The virulence of the microbe, which differs in different countries; (2) the extent to which the patients have become immune through natural selection. In other words, the microbes, as the result of their struggle with men, gradually increase in strength; natural selection evolves more powerful microorganisms. On the other hand, a race of men is evolved more capable of resisting them. The resultant

represents the malignity of the disease, and it will vary as the factors vary. Dr. Effertz then notices two remarkable facts:-(1) African malaria is deadly for Europeans, but very mild for Africans. (2)
American malaria is deadly for American Indians,
but mild for Europeans. He infers (a) that
the African parasite has grown more virulent
during the thousands of years it has been in Africa; (b) that the American parasite is much less virulent, having been recently carried to America. The African negro has won his battle; the European has partly won it; the American Indian has yet to win it. The European is superior to the American parasite, but inferior to the African parasite. The Indian is inferior, the African negro superior, to both.

Dr. Effertz applies similar reasoning to syphilis and yellow fever. He shows that the Spaniards could not have carried out their conquests if the Continent had been as fever-stricken as it is now, and as a matter of fact history tells us little about fever in those days. Malaria was probably brought over from Europe; it now kills over 50 per cent. of all Mexican Indians.

America, by way of return, gave syphilis to Europe.

I am, Sir, yours truly,

W. H. S. Jones.

[We insert our correspondent's interesting letter in the hope that it may bring forth some comment from those who have had special experience of the subject. -ED. M. P. AND C.1

# OBITUARY.

PERCY BOULTON, M.D.EDIN., WE regret to announce the death, after a long ill-

Seymour Street, W., in his 68th year.

Dr. Boulton was educated at Beverley Grammar School and at Edinburgh University, where he took the degree of M.D. In 1863 he began practice at Western and two westerns are to London Worksop, and two years later he came to London. For 30 years he was a physician to the Samaritan Free Hospital, and afterwards he was elected consulting physician. He had also been a physician to Queen Charlotte's Hospital, and was a cophysician to the British Home for Incurables. consulting

Dr. Boulton devoted much of his time in later life to the question of the compulsory registration of mid-wives, and he took an active part in the passing of the Midwives Bill in 1902. For nine years he was a member of the Obstetrical Society's board for the examination of midwives, and for four years he was

# SIMEON HOLGATE OWEN, M.D., R.U.I., M.R.C.P.

WE regret to record the death of Dr. Simeon Holgate Owen, which occurred on May 19th. Dr. Owen was one of the best known physicians in Manchester. The son of the late Mr. Henry Owen, dental surgeon, he was born sixty-five years ago, and took his degree in 1872 at the Royal University of Ireland. Dr. Owen was always in close touch with the various medical institutions of the city. He was President of the Manchester Clinical Society, Consulting Physician to the Manchester Northern Hospital for Women and Children, and Assistant Physician to the Infirmary, while before its incorporation he was also the Medical Officer for Moss Side. Dr. Owen lectured several times before the Sanitary Association, and, apart from various medical articles, he wrote much on literary

# SPECIAL ARTICLES.

# THE TWELFTH INTERNATIONAL CONGRESS ON ALCOHOLISM, London, 18th to 24th Ju'y, 1909.

THE object of this Congress, of which H.R.H. the Duke of Connaught is Honorary President, and the Right Hon. Lord Weardale Acting-President, is to consider the Causation, Prevention and Cure of Alcoholism, from both their individual and national aspects, in the light of research and experience afforded by the universal interest in the problem of Inebriety which prevails throughout the world. The arrangements for the Congress are now in a forward state, and a considerable number of members has been enrolled representing the Temperance forces of all degrees in nearly every European country, as well as in the United States, India, and our Colonies.

His Majesty's Government are taking considerable

interest in the Congress, and are giving the official reception at the Imperial Institute on the opening night, when the First Commissioner of H.M. Works, the Right Hon. Lewis Harcourt, M.P., will receive the members, and the Representatives of Foreign and Colonial Governments who have appointed delegates on the invitation of our own Foreign, Indian, and Colonial Ministers.

The proceedings will commence on Sunday, July 18th, with the official sermon, to be preached by the Right Rev. Bishop of Croydon at the afternoon service in St. Paul's Cathedral. The headquarters of the Congress will be the Imperial Institute, South Kensington. The Congress sittings will take place in the Kensington Town Hall, in the Conference Room at the Imperial Institute, and in the Theatre of the Victoria and Albert Museum close by.

The first general meeting on the Monday morning

will be devoted to the Inaugural Address of welcome by the Acting-President, Lord Weardale, and to brief speeches in response from Governmental and Tempespeeches in response from Governmental and Temperance representatives of foreign countries and the Colonies. This will be followed in the afternoon by the formal opening of the Exhibition by the Very Rev. the Hon. Dean of Hereford, Chairman of the Conveners, and in the evening by the Grand Official Reception. During the week there will be many other social engagements to interest sections of the membership; these will include, as already arranged, a reception of medical members by the British Medical Temperance Association at the London Temperance Hospital; breakfasts by several important committees; and a Masonic reception by the London Temperance

The scientific side of the International Congress has always received a considerable share of attention, and on this occasion a series of sectional meetings on the Tuesday, Wednesday, and Friday of Congress week has been allotted to it. Among the distinguished foreign members who will contribute papers are: Professor Taav. Laitinen, M.D., Helsingfors, who, in addition to his "Norman Kerr Lecture," under the auspices of the Society for the Study of Inebriety, on "The Influence of Alcohol on Immunity," will make "A Further Contribution to the Study of the Influence of Alcohol on the Degeneration of Human Offspring" in continuation of his remarkable deliverance at Stockholm in 1907. Dr. A. Holitscher, Carlsbad, will report on "Alcohol in Lobar Pneumonia and Enteric" and on "The Consumption of Alcohol in Hospitals and Asylums"; Dr. Legrain, Paris, will deal with "Alcohol and Insanity"; and Dr. Stein, of Budapest, with "Alcohol and the Nervous System."

The opportunity for foreign scientists to hear their

British confreres being but infrequent, the services of several well-known exponents of ascertained facts upon several well-known exponents of ascertained facts upon the alcohol question have been secured. Among the subjects to be treated by them are: "Alcohol and Temperance," by Professor G. Sims Woodhead, M.D., F.R.S.Ed., Cambridge; "The Action of Alcohol on Muscular and Mental Fatigue," by Dr. W. H. R. Rivers, F.R.S., Cambridge; "The Resistive Power of the Brain Against Alcohol," by Professor Clouston, M.D., Edinburgh; "The Effects of Alcohol on the Nervous System as Exhilibred in Hospital and Asylum Practice," by Dr. F. W. Mott, F.R.S., London.

The economic aspect of the problem of alcoholism

The economic aspect of the problem of alcoholism will be considered at the fourth general meeting on the Thursday morning, at which an important contribution will be made by the Right Hon. Sir Thomas P. Whittaker, M.P., on "The Economic Effects of the Production and Consumption of Alcohol." The discussion upon this will be followed by two papers on cognate subjects, viz.: "The Alcohol Problem in the Light of Vital Statistics," by Herr Hansen of Kiel; and "Alcoholism and Industrial Assurance against Disaster and Invalidity," by Herr Karl Kögler, of Vienna. Considerable interest attaches to these papers as their topic is engaging the attention of many social reformers in this country; a number of German, Austrian and Hungarian members have expressed a desire to speak, and it is evident that some valuable information from official sources will be given to the Congress.

The Treatment of the Disease of Alcoholism on its preventive as well as its remedial side will engage the attention of the Congress on the last two days. The legislative aspect will be presented by Alderman F. S. Spence, of Toronto, and Professor Jensen, of Bergen, who will deal respectively with the "No Licence" and the "Management" methods; while the International Question in regard to "Native Races" will be dealt with by Herr Vietor, of Bremen. These subjects will occupy the fifth general meeting and an afternoon session on the Friday; and on the Saturday at the sixth general meeting the "Conclusion of the whole matter," from what may be called the Home Office point of view, will be presented. "Alcoholism and Crime," by Lieut. Colonel A. B. McHardy, Edinburgh, Chairman of the Prison Commissioners for Scotland; "Treatment of the Criminal Inebriate," by Professor G. Aschaffenburg, of Cologne, and "Legislation for the Inebriate," by Dr. R. W. Branthwaite, H.M. Inspector under the Inebriate Acts, are the names of papers and readers.

There will, of course be public demonstrations during Congress week; there will be at least one of great interest, which will take place on the evening of Wednesday, July 21st, in the Queen's Hall, under the presidency of the Right Hon. Lord Alverstone, Lord Chief Justice of England. Full information will be published in good time, meanwhile application for membership should be made to the Honorary Registrar, care of the National Temperance League, Paternoster House, London, E.C. The subscription is 10s.; a contribution of half that sum entitles an "Associate" to receive a copy of the Congress report and cards for the public engagements only. Donations to the necessarily heavy expenses will be duly acknowledged by Mr. J. S. Higham, M.P., Chairman of the Finance Committee, if sent to him at 14 St. James's Court, Buckingham Gate, S.W.

# MILITARY & NAVAL MEDICAL NOTES.

A QUESTION has been raised owing to the exchanges allowed between officers of the Royal Army Medical Corps and the Indian Medical Service. The War Office has recently sanctioned an exchange between Captain H. P. G. Easton, I.M.S., and Captain H. G. S. Webb, R.A.M.C. What is to be the relative position, asks the *Pioneer Mail*, in respect of Service standing which these officers will hold in the respective spheres to which they have been transferred, assuming that the date of their first appointment and of their present rank is not identical, and that upon admission to the Service each of them did not occupy a position identical in order of merit with their contemporaries immediately above and below each of them respectively?

A GOOD, wholesome order has been issued to prevent young bandsmen and the like in the Army from smoking. It is directed that no tobacco, cigars, cigarettes, or smoking material of any kind are to be sold or supplied in regimental institutes to any person under the age of 16 years, and no such person is to be allowed to smoke in any part of the institute. Some control even over the strength of the tobaccos sold in regimental canteens or institutes to soldiers might, we think, result in good.

A PRETTY good lesson has been imparted to a Private Alexander of the Gloucester Regiment in Bombay.

This soldier with two companions went to the Victoria Gardens and began to indulge in the insensate and dangerous habit of teasing a lion with a stick, when the beast seized him with its paws dragging him against the bars of the cage. Private Alexander received severe injuries to his right arm and a number of wounds on various parts of his body before he could be freed from the clutches of the infuriated beast. He was rescued with difficulty, and was in hospital, where he will have ample time to reflect.

WE have already twice alluded to the correspondence in the Naval and Military Record on "Nursing in Naval Hospitals." In the issue of that paper on the 13th inst. a "Matron of Long Experience" in a Civil Hospital expresses in a letter her surprise at the existing duty arrangements in Naval Hospitals. If there are grave defects, how is it no Member of Parliament has been asked to interrogate the First Lord of the Admiralty?

NON-DIETED observation hospitals have now been opened at Bulford, Darrington and Rollestone Camps, under arrangements made by the Royal Army Medical Corps at Tidworth for the Regular troops now under canvas at these centres.

MAJOR F. W. CORNWALL, I.M.S., Director of the Pasteur Institute, has left Coonoor, in the Neilgherries, for Australia, having teen medically advised to take a sea voyage. Major R. Bryson, I.M.S., Medical Officer at Coonoor, officiates as Director.

THERE has been a great commotion over the promotion of Colonel C. B. Lukes, I.M.S., to be successor to Surgeon-General Bomford as Director-General of the Indian Medical Service. This officer has been indeed favoured, having passed over the heads of several of his seniors in the I.M.S. The only parallel to this rapid advancement was, some years ago, the promotion of the present Director-General Army Medical Service.

# REVIEWS OF BOOKS.

ROSE AND CARLESS' SURGERY. (a)

WE well remember the favourable reception this Manual of Surgery by Rose and Carless received when it was first published in 1898. In a very short time it seemed to be generally recognised as the book for students on the subject. It has now reached its seventh edition, and no greater proof of its deserved popularity can be mentioned, than that it has been found necessary to re-edit, or reprint it each year, with the exception of 1003, since it first appeared.

with the exception of 1903, since it first appeared. Rose and Carless' Surgery is so well known now by the profession, that a detailed account of the text, illustrations, and general get up of the work, is hardly necessary. However, for the benefit of those who may not be already acquainted with this manual, we may say that it not only contains all that is necessary for any pass examination in surgery, but that it is a work that can be consulted later with the assurance that one will obtain all such information as is likely to be of practical use in considering the diagnosis and treatment of cases. The first chapter deals with Surgical Bacteriology, Infection, Immunity, and constitutes a very fitting introduction to the succeeding chapters, which are devoted to Inflammation, Gangrene, etc. The chapter on the general technique of operative surgery requires special notice, on account of its practical utility and completeness. In this connection it is convenient to draw attention to the ex-

<sup>(</sup>a) "A Manual of Surgery for Students and Practitioners." By William Rose, M.B., B.S.Lond. F.R.C.S., Emeritus Professor of Surgery and Member of Council, King's College, London, and formerly Senior Surgeon to King's College Hospital, etc., and Albert Carless, M.S.Lond., F.R.C.S., Professor of Surgery in King's College, and Surgeon to King's College, Hospital, London, Examiner in Surgery to the University of London and to the Viotoria University of Manchester, etc. Seventh Edition. University Series. London: Bailliere, Tindall and Cox. Price 21s.

cellent descriptions, accompanied by the necessary anatomical details, of special operations, which will be found throughout the book. The next chapters discuss the diseases and injuries of various tissues. It is a decided recommendation in a book of this kind to have one subject treated and dismissed in one chapter, or in two consecutive chapters, as the case may be, and not scattered through a work, as we often find it elsewhere. For instance, Chapter XIII. gives a complete account of the surgery of veins, and Chapters XXIII. and XXIV. of injuries of the spine and diseases of the spine. The descriptive power of the authors is perhaps best shown in their discussion of abdominal surgery. One cannot fail to be impressed with the graphic account of intestinal obstruction, and of the various surgical conditions of the kidney. Chapter XLIII. on amputations is a more exhaustive treatise on the subject than is usually found in a general surgery. All the more common operations are given in detail. The last chapter gives an account of local, spinal and general anæsthesia. The book contains a very full index for reference, occupying pages 1329 to 1376, inclusive. The seventh edition has several new illustrations, mostly dealing with the X-ray appearances of fractures, and photo-micrographs of the histology of tumours. Also fresh material has been added, especially in connection with bacterial vaccines and opsonins.

On account of the consecutive arrangement of the subject matter, and the lucid style in which this book is written, Rose and Carless' Surgery is a particularly easy one to study, and from which to acquire a really sound knowledge of the principles which underlie modern surgery, and of the significance of clinical observations. The practitioner will find here a concise and thoroughly practical description of surgical conditions and their most effective treatment. We can therefore confidently recommend this manual of surgery both to the practitioner and student. It is well printed, judiciously illustrated, is convenient in size, and is altogether the most satisfactory book of its kind on the subject before the profession. We heartily congratulate the authors and the publishers on their excellent work.

# THE NAUHEIM TREATMENT OF DISEASES OF THE HEART AND CIRCULATION. (a)

That this little book is popular—and, we think, deservedly so—is shown by the fact that already a third edition has been found necessary since it was first published in 1904. In it the author explains clearly and in detail the manner in which the Nauheim treatment may be successfully employed at home, thus increasing its sphere of usefulness and bringing it within the power not only of those who cannot afford to go to the spa, but also of those who require its aid during the time when Nauheim is not available. There is, of course, much difference of opinion as to the value of this method of treatment, but we note that the author does not claim for it the unreasonable position in which many of its more fanatic supporters would place it.

The resistance movements, so difficult to understand from any written description, are rendered very obvious and easy by a series of good illustrations. confess that the last chapter, which contains the records of cases successfully treated, does not seem to us to favour the author's contention, for some of the diagrams which illustrate the reduction of the cardiac dulness, appear to show that the heart's dimensions after treatment are much smaller than normal. Yet cardiac atrophy, if it could be induced, would scarcely be beneficial. Again, in Case No. 4, that of a patient said to be the subject of aortic stenosis and mitral regurgitation, we should have thought that the presence of the apex beat within the nipple line after treatment, and the pulse tracing given, which shows a sharp apex and a distinct dicrotic notch, would of themselves refute the diagnosis. The book is well bound and printed, and fills a long-felt want.

### ORGANIC MATERIA MEDICA. (a)

THE last edition of this work has been out of print for some time, and in the present issue the opportunity has been taken of bringing it thoroughly up-to-date, especially those parts relating to chemistry and the physical and other characters of the drugs mentioned. Those characters which are common to each group are carefully described by way of introduction to the various groups, such as roots, barks, leaves, volatile oils, resins, etc. The volume deals not only with official remedies, but also with many which are not included in the British Pharmacopæia. Under each crude drug we find notes regarding its official characteristics, habitat, chemistry, uses, and preparations. The classification adopted is not the purely botanical one, but drugs of analogous form and physical character have been grouped together. In the present edition the work has been greatly improved and considerably extended, and doubtless it will continue to be the standard handy reference volume on its subject, as its predecessors have been. The work of revision has been thoroughly and effectively carried out, so that it comes as near perfection and completeness as one can expect in a book which covers so much ground within the compass of less than 400 pages.

#### DISEASES OF THE HEART. (b)

As might be expected by anyone who has followed Dr. Mackenzie's writings on cardiac disease as they have from time to time appeared in the medical journals, his book on diseases of the heart approaches the subject from a different standpoint to that of the older treatises. Discarding the plan of taking up each lesion separately and analysing the signs and symptoms to which it gives rise, he adopts the method of describing the symptoms of heart disease as they present themselves to patient and physician. The result is one of the most noteworthy contributions to the science of medicine that has fallen from the pen of any English writer for many years; and those who now for the first time become acquainted with Dr. Mackenzie's work will not fail to appreciate how great has been the advance in our knowledge of cardiac pathology during late years—an advance for which he, more than perhaps any other student of the subject, is materially responsible.

The book opens with chapters giving a good summary of modern teaching on the physiology and anatomy of the heart, and then proceeds to the discussion of subjective symptoms. Under this category comes pain, and in the chapter on angina pectoris Dr. Mackenzie offers good reasons for believing that the immediate factor in producing the attacks is exhaustion of the function of contractility of the heart. In connection with this subject the question of visceral pain generally is considered. Instrumental methods of examination are fully described; in particular the polygraphs invented by the author. Hæmometric methods do not rank high in his estimation. Much space is devoted to the interpretation of graphic tracings, and Dr. Mackenzie must be most cordially congratulated on the clarity of his exposition of what is really no easy subject to follow. This part of the book is unquestionably hard reading, but well repays the close study it requires. The difficulties are inherent, and even Dr. Mackenzie's lucidity does not banish them all. We next come to what are undoubtedly the most important and fascinating chapters in the book-those on cardiac irregularity. The modern classification into five main varieties is followed—sinus irregularity, extra-systole, nodal rhythm, defect of conductivity, and depression of contract lity. This is the same as Hering's grouping, though the nomenclature differs. It is not too much to say that a knowledge of the meaning of these irregularities is indispensable to intelligent treatment, and that their recognition constitutes almost as great an advance in the

<sup>(</sup>a) "Southall's Organic Materia Medica." By John Barclay, B.Sc. Lond., F.C.S. Seventh Edition. Revised and enlarged by Ernest W. Mann, Pharmaceutical Chemist, sometime External Examiner in Materia Medica and Pharmacy to the University of Birmingham. London: J. and A. Churchill. 1909.

(b) "Diseases of the Heart." By James Mackenzie, M.D., M.B.C.P. London: Henry Frowde and Hodder and Stoughton. 1908.

study of heart disease as did the introduction of the stethoscope in the diagnosis of bruits. The later chapters of the book deal with arterio-sclerosis, valvular defects, congenital heart disease, heart disease in

pregnancy, and other subjects.

It is impossible to withhold a word of admiration for the enormous mass of observations this book represents, and it is little short of marvellous that they should have been made by one engaged in arduous general practice. But while this is so, the book could never have been written by a man whose experience was limited to hospital and consulting work. apparent throughout, particularly in Dr. Mackenzie's estimates of prognosis. He was able to watch his cases, not for months, but for years at a time, and has arrived at a judgment as to the gravity or otherwise of various signs and symptoms which differs somewhat from current teaching. The paragraphs on treatment are short, but to the point. They are, perhaps, open to the criticism of being as often destructive as constructive, but it is necessary to pull down before one can build up, and no doubt Dr. Mackenzie will some day remedy the defect. His remarks on Nauheim baths and the like are outspoken in the extreme; they ought to do some good in checking the exploitation and uncritical employment of these and other equally vaunted lines of treatment.

# LITERARY NOTES.

"NEW AND NON-OFFICIAL REMEDIES" is the title of a small book, descriptive of those drugs which have been accepted by the Council of the American Medical Association on Pharmacy and Chemistry prior to January 1st, 1909. The acceptance of the preparations included in this book has been based in part on evidence supplied by the manufacturer, and in part on investigations made by the Council. This volume is to be issued annually in future. Each article is followed by a brief description of its physical and chemical characters, its actions, uses, and dosage, together with the name of its manufacturer. There are many drugs, not included in the B.P. or U.S.P., which are of great value in medicine. These are all mentioned here. Thus we find our old friends ichthyol, heroin, sublamin, styptol, etc., which are often for-gotten or even unheard of by practitioners in this country. We trust this handy volume will tend to popularise many of the really valuable drugs recently introduced, but too little known as yet by the general

"THE CHILDREN'S CHARTER" is the title of a handy statement of the Children Act. It is written by M. K. Inglis, and published by Messrs. Thomas Nelson and Sons, at 6d. net. It is specially intended as a guide for social workers, and, as such, will doubtless prove of considerable value.

FROM Messrs. Bale, Sons and Danielsson comes an interesting little book entitled "Notes and Thoughts from Practice," by Dr. W. J. Tyson, of Folkestone. After many years of practice, the author gives us some of his own personal experiences of diseases and their ætiology, as well as their treatment. He strongly advocates greater clinical observation in these days, and maintains that hospital appointments ought to be paid. There is a great deal of common-sense in his remarks, and the book forms interesting and suggestive

WE have received the year book of the Universal Medical Esperanto Association (Tutmonda Esperanta Ruracista Asocio). It is well printed and illustrated with the most recent photograph of Dr. Zamenhof, the inventor of the language, it contains the report of the Hon. Secretary, Dr. Robin, of Warsaw, who states that he is thoroughly satisfied with the result of his suggestion made in La Vocho de Ruracistoj of June last, to found a medical association. The list of members shows that in the first 41 months there were

over 425, and we are informed that over 200 have since joined. From the list of consuls it would appear that practically every country in the world is already represented. Among the contents is the report of the International Committee of the Red Cross on the fourth (Dresden) Esperanto Congress, strongly recommending Esperants to all Red Cross Associations in the world, and giving an account of an interesting experiment carried out by Dr. Thalwitzer who, in ten lessons, succeeded in instructing a section of thirty men of the Saxony Red Cross, so that they could give and take orders, ask and answer questions in Esperanto, while giving a display of ambulance work. Generals Schmidt and Rühlemann (Germany), General Sebert (France), Major Straub (official delegate of U.S.A.), Dr. Kroita (Japan), Dr. Thalwitzer, and Dr. Zamenhof were present. The volume concludes with an article on Medical Terminology in Esperanto. Reference is also made to the Esperanto section which is being organised for the International Medical Congress at Budapest in August next.

# LABORATORY NOTES.

### GLIDINE AND IODOGLIDINE.

GLIDINE is a pure vegetable protein food, containing Lecithin, and practically free from carbohydrates. It is prepared from wheatmeal by a process combining centrifugalisation and a washing-out. The albumen thus isolated forms about 96 per cent. of the Glidine, the remainder being Lecithin and nutritive salts. As thus prepared Glidine is a fine yellowish-white powder, tasteless, and insoluble in cold water. It is claimed to be even more digestible than meat albumen, and to possess a facility of absorption, rendering it very suitable as a nutrient for convalescents from debilitating illnesses. It can be administered in a variety of vehicles: coffee, tea, cocoa, beer and milk. Emphasis is laid on its freedom from carbohydrates and "extractives.

In Iodoglidine, the iodine exists chemically combined with the wheat protein. Our analysis shows it to contain no free iodine and but a small amount of iodide in ordinary combination. It thus presents a marked advantage over the alkaline iodides. A minute amount of iodine is liberated in the stomach, the separation taking place almost entirely in the intestine. Some experiments we have made seem to show that the absorption of the iodine is slow and gradual, and we find the excretion of the iodine in the urine to be During the first twenty-four hours no very slow. iodine could be detected in the urine, a little was found during the second twenty-four hours, and, at the time of writing, which is during the third twenty-four hours after administration, an appreciable quantity of iodine is being excreted. These results confirm the elaborate experiments carried out by Continental workers, and seem to account for the fact that when iodine is administrated in this combination. when iodine is administered in this combination much less is required than when the alkaline iodides are used when the excretion of iodine begins a short time after ingestion and reaches its maximum in 24 hours. In addition, we gather that this Iodoglidine can be prescribed without fear of resulting "iodism."
We are favourably impressed with both of these preparations of Messrs. Menley and James, Limited.

# CAMPBELL'S CONDENSED SOUPS.

WE have examined tins of the mulligatawny and tomato soups as prepared by the Joseph Campbell Company. We find these soups to be free from boron preservatives and poisonous metals, and when prepared, to form appetising dishes. Some idea of the amount of concentration can be obtained from the fact that the tomato soup contains 14 per cent. and the mulligatawny 18 per cent, of dry solid matter. The flavour of these soups is excellent, and their preparation entails a minimum of trouble. The purchaser has a large selection of soups to choose from, and the manufacturers lay great stress on the searching cleanliness obtaining in the Campbell establishment. The English Agency for these soups is at 6-8 Bouverie Street, London, E.C.

#### SUMMARY RECENT MEDICAL LITERATURE, OF English and Foreign.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

The Pathology of the Red Degeneration of Uterine Myomata.—Lorraine Smith and Shaw (Journ. Obst. and Gyn. of the British Empire, XV., 4.) Based on the examination of five specimens, the first point investigated was the possible relation of the redness to the extravasation of blood either recent or of old standing. The sections gave no evidence of the presence. ing. The sections gave no evidence of the presence of recently extravasated red corpuscles so generally distributed as to explain the colour, nor was there evidence found of either hæmosiderin or free iron. Sections examined from the reddened areas and from areas which still remained of the ordinary colour were stained with Weigert's fibrin stain, and showed thrombosed vessels in the red areas, but none in the areas which were of normal colour. There was nothing found to contradict the hypothesis that the condition is associated with thrembosis throughout. The occurrence of thrombosis would lead to an increase in the size of the tumour, and this might explain the pain which was observed to accompany the increase in size. The authors consider pregnancy a probable predisposing factor in the causation of the condition, and that obstruction to the circulation might arise from pressure, or in the puerperium might be associated with the increase in coagulability of the blood which is said to occur. The tissue in which thrombosis takes place was not of the ordinary myomatous type in any of the specimens. The strands and bundles of muscle fibres were found to be in a condition of atrophy and degeneration, and had disappeared completely over considerable areas, their place being taken by a homogeneous substance which stains faintly with eosin, but otherwise presented no histological characters, this seemed to consist of the débris of the atrophied tissues, and was seen in the first instance in the neighbourhood of the blood vessels; frequently a blood vessel with a healthy wall was seen surrounded by an area of homogeneous material separating it from the muscular bundles which had not been attacked. In the tumours examined, where red colouration had occurred, this process of degeneration was present, and while it gave a general appearance of softening to the tumour the horse was represented and appearance of softening to the tumour them. change was never advanced and no definitely localised areas of softening were visible. Special attention was paid to the presence of fatty degeneration in the Special attention was paid to the presence of latty degeneration in the reddened tissues, and fat was found in considerable quantities in the breaking down fibres and wandering cells, and in cells round the thrombosed vessels, but the authors look upon the increase of fat not as indicative of increased activity in breaking down, but rather to an arrest in absorption. The authors conclude (1) that the change consists in thrombosis of the blood vessels. (2) This may commence at the periphery of the tumour. (3) The tumours are also in a state of degeneration. (4) The fat and fat crystals are probably derived from breaking up of muscle. (5) The tumours are liable to become infected and so cause toxic symptoms. (6) Pregnancy is probably a predisposing factor.

Hernias Through the Pelvic Floor.—Barrett (Amer. Journ. of Obst., LIX., 4). The author considers the embryological development of the pelvic diaphragm, and also points out the changes in the muscular arrangement of the lower animals and man, especially that of the levatores ani. He points out that some cases of prolapse where there has been no injury to the pelvic floor may be due to a reversion to the earlier type. He points out that hernia through the vaginal outlet is provided against by a strong posterior segment with a superimposed more movable anterior segment with the vagina running obliquely, so that forces from within press the anterior segment against the posterior. With the levator ani muscles injured

the anus and perineal body drop backward, leaving no support for the anterior segment which gradually gives way. Too often the efficiency of the perinæum has been considered to depend upon the cutaneous has been considered to depend upon the columneous structure, perineal body and mucous membrane, which are really of very minor importance, the perineal body only acting as a fixed point for the muscles to act upon. A traumatism of the pelvic floor may act upon. A traumatism of the pelvic floor may separate the preanal fibres of the levator ani, or may injure the anterior portion of the muscle or the muscle may be torn from its origin. These injuries may occur without tearing of the skin or mucous membrane and so be unnoticed, but they are the forms of tears which destroy the efficiency of the pelvic floor. The author gives the technique of a method for repairing the pelvic floor with a view to restoring the parts and enabling them to fulfil their function according to the authorizations he has pointed out. to the anatomical lines he has pointed out.

Amputation of the Uterus in the Corpus to Preserve the Menstrual Function.—Kelly (Amer. Journ. of Obst., LIX., 4). Having noticed that occasionally fibroid tumour cases, in which the ovaries had been left, but the uterine body had been removed with the tumours, would show a tendency to menstruate regularly for some months, and further that the patients were free from the marked discomforts of the artificial menopause, and were in better condition than those who had no menstruation. The author in selected cases proceeded on a plan of keeping a portion of the uterine body with the mucous membrane above the cervix in women who were still menstruating, and in this way succeeded in preserving regular menstruation in many cases. The two classes of patients best suited for this plan of treatment are those with fibroid uteri not suited for myomectomy, but not demanding panhysterectomy and those with subinvoluted hæmorrhagic uteri. It is sufficient to retain a little pocket of mucosa big enough to lodge the end of the little finger, or more if possible, with the corresponding muscular or more it possible, with the corresponding muscular tissue. The amputations are graded from those which are barely supra-cervical to those which are at the very fundus and are principally a myomectomy. The author has practised two styles, one horizontal and the other vertical. The amputation carried out by either of these methods leaves a little uterus which continues to menstruate moderately, and obviates the unpleasant sequelæ of the more radical operations. The author reports nine cases treated in this way with their after histories. their after histories.

A Preliminary Report on the Use of Bacterial Vaccines in the Treatment of Septic Infections.—Oastler (Amer. Journ. of Obst., LIX., 4). The report of five cases treated—four with success, and one not benefited the writer sums up as follows:-Apparently favourable clinical results have been obtained in the use of vaccines of streptococci, staphylococci, B. coli, B. mucosa and gonococci. All but gonococcus vaccine should be autogenous. Vaccines are not cure-alls, but seem to aid materially in combating the septic process. Vaccines are required where the blood shows poor resistance, i.e., low leucocyte count and high polymorphonuclear. In violent cases of acute sepsis no resistance can be created. The dose, site of injection and frequency was only problematic and experimental. Too large a dose does harm, small doses give better

A Case of Primary Sarcoma of the Vagina.—Maclean (Journ. of Obst. and Gyn. Brt. Emp., XV., 4). A girl of fifteen years of age complained of shooting pain in the left lower abdomen, dysuria, and the pressure of a soft mass at the ostium vaginæ. The

swelling had been noticed about one month. Protruding from the vagina was a dark red, soft, non-friable, papillomatous growth of the size of a tangerine orange; its surface like a cluster of currants. The attachment of the growth was about one inch broad, and extended from one inch posterior to the orifice of the urethra, to within one inch of the cervix on the anterior vaginal wall. The growth was removed and the base cauterised, but recurrence developed within six months. The stromal tissue appears mainly to be composed of a mass of cells with deeply staining nuclei and ill-formed blood vessels. The cells are both spindle and round, and of varying dimensions, some almost giant cells. The writer supplied a photograph of the tumour in situ, and two microphotographs of sections.

Comparative Rarity of Primary Carcinoma and Sarcoma of the Vagina.—Macnaughton-Jones (reprints). The writer points out that the total number of cases of undoubted primary carcinoma of the vagina has not yet reached two hundred. He gives the report of several interesting cases and the replies which he received in 1907 from several of the largest clinics in Germany. He quotes the clinical and histological facts pointed out by Williams:—(a) Vaginal irritation does not appear to play a part in its production. (b) Nearly all primary vaginal cancers appear to be of the squamous, epithelial, or epidermoidal type. (c) That vaginal cancer may be divided into tubular and lobular. (d) The posterior wall and upper part of the vagina is the most common site. (e) The most common period of occurrence is after the menopause. The Continental statistics collected give the frequency at under 2 per cent. of all cases of carcinoma of the female genitalia. The youngest cases on record appear to be Guersant's, aged 31 years; Johanowski, of years; and Smith's, 14 months. Cases are recorded where the wearing of a pessary seems to have produced the disease, as Maly's (Centrabl. f. Gyn., 1903), where a pessary was worn for 39 years, and the growth occurred in a furrow corresponding chactly to that of the ring. Petersen (Amer. Journ. Obst., 1903) recorded a case, aged 84 years. Primary sarcoma appears to be considerably rarer than carcinoma. The first case was reported in 1872, and up to 1899 only 32 cases were recorded, and from that up to 1904 only eight more were added. The record of non-recurrence after operation is low. Five are known to have been free from recurrence at periods of from 11 to 2} years after operation; two are stated to be free from recurrence, but the time is not stated; and two were of still relatively short periods; two the result is not known; two died at operation; three were not operated upon, and twenty-four recurred. The seat of the disease appears to be slightly if at more commonly the posterior than the anterior wall, and the age of patients generally under 40, a large number of cases being under 30, and cases are recorded in children 18 and 25 months of age. F.

Vaccines in Typhold.—Walters and Eaton (Boston Medical and Surgical Journal, April 22nd, 1909) publish information as to the results of the treatment of typhoid fever by vaccines of dead bacilli. They state that of 77 cases of typhoid treated in the Massachusetts Hospital in 1908, 31 were treated by vaccines, the remainder receiving only the regular routine of dietetic, hygienic, hydrotherapeutic, and drug measures in vogue. No selection of patients was made. In no case was anyone observed to be ill as the result of the vaccines, while the mortality among those thus treated was 3.2 per cent., as contrasted with a mortality of 11.1 per cent. among those not so treated. The authors give details of a few cases, but do not tell us the dose of vaccine employed.

# MEDICAL NEWS IN BRIEF.

An Unqualified Midwife.

AT Battersea, on the 20th inst., Mr. John Troutbeck conducted an inquiry with reference to the death of

a child named Charles James Albert Ellis, aged four weeks. The parents live at Battersea, where, it was stated, seven persons inhabited two rooms. The father of the child had been out of work for a long time. The mother stated that when she engaged a Mrs. Rollings as nurse she understood that she was certificated. Mrs. Rollings said her husband was a labourer, working for the Battersea Borough Council. She had no certificate and had never been trained, though she had done nursing for 36 years. In this case she used an ordinary pair of household scissors and afterwards noticed an abnormal appearance, but she did not call a doctor because she considered the parents had no money. She told Mrs. Ellis she had no certificate; she did not realise it was wrong for her to attend such cases. Medical evidence showed that death was due to blood poisoning, and that the septic condition might have been set up through the use of the scissors. The jury returned a verdict in accordance with the medical testimony, and held that Mrs. Rollings should be severely censured for having failed to advise the calling in of a doctor. The Coroner said he was informed that on a former occasion Mrs. Rollings had promised the County Council inspector that she would cease to attend cases. The condition of affairs was such that the Council might possibly think it their duty to take further action under the provisions of the Midwives Act.

# The Crusade against Bogus "Deutists" in Ireland.

DURING the past week a man named Byrne was prosecuted by the Secretary of the Irish Branch of the British Dental Association for infringement of the Dentists' Act, 1878. The infringement consisted in the terms of Byrne's advertisements, which, according to the summons, implied that the defendant was a person specially qualified to practice dentistry. After hearing the evidence, the magistrate imposed a fine of £5 on each of the two summonses, with 3 guiners costs

### The National University of Ireland.

THE Dublin Commissioners appointed under the Irish Universities Act, 1908, to make Statutes for the general government of the University have now done so, and the Statutes were issued to the Press on Friday last. They provide for the examinations and degrees of the University, and for the officers and the payment of officers of the constituent Colleges. So far as the medical schools of the Colleges are concerned, the professorships seem to be similar to those in other Universities. Perhaps the most striking part of the Statutes is that dealing with the teaching of Irish and other Celtic languages. In the three schools at Dublin, Cork and Galway something like £3,400 a year is to be spent in doing this, and according to the Freeman's Journal, in the case of the Dublin College, "over a tenth of the whole endowment of the College is assigned to its Irish departments."

# Society for the Relief of Widows and Orphans of Medical Mea

THE annual general meeting of the above Society was held at 11 Chandos Street, Cavendish Square, on Thursday, May 20th.

In the absence of the President, Mr. J. Warrington Haward, the Acting Treasurer took the chair. Twenty

members were present.

The Society's invested funds amount to £100,071, from which was derived in interest the sum of £3,121 17s. 1d.; £645 being received in subscriptions and donations.

During the past year the sum of £3,017 was distributed amongst the annuitants of the charity-namely, 48 widows and 16 orphans, each widow receiving on an average £50, besides an additional £10 as a Christmas gift, and each orphan £12 and a gift of £3 at Christmas.

The Copeland Fund is a special fund which enables

The Copeland Fund is a special fund which enables the Society to grant to any widow or orphan already in receipt of the Society's ordinary relief, extraordinary assistance in special circumstances of unusual distress, such as blindness, paralysis, insanity, severe disabling accident or grave permanent disease, and to continue such extra relief in the case of orphans beyond the age of sixteen or eighteen years (at which under the Society's existing by-laws, the ordinary relief ceases) for such further period as the Court of Directors may

During the year two widows in receipt of grants died. During the year two widows in receipt of grants died. One, whose husband had paid in subscriptions £19 19s., received £1,500, the other, whose husband had paid in annual subscriptions £31 10s., received £3,300; she had been in receipt of grants since 1855. Two new widows were elected during the year, and on December 31st there were 47 widows and 15 of phans in receipt of grants.

One of the widows has been on the books since 1854,

and has already received over £,2,200.

Relief is only granted to the widows and orphans of deceased members, who have paid their annual subscription for three years, or who are life members. During the year nearly fifty letters were received from widows of medical men, who, in many instances, had been left practically penniless, asking for relief, but this had to be refused, as their husbands had not been members of the Society.

The directors cannot too strongly urge upon the members of the medical profession, especially the younger, the desirability of joining the Society. Membership is open to any registered practitioner who at the time of his election is resident within a 20-mile radius from Charing Cross. Should any member 16move beyond the limits of the Society, he nevertheless continues to be a member.

The annual subscription is two guineas; every member who has paid this sum for twenty-five years becomes a member for life. Life membership may also be obtained by the payment of one sum, varying with the age of the applicant.

Further particulars and application forms may be obtained from the Secretary at the Offices of the Society, 11 Chandos Street, Cavendish Square, W.

A cordial vote of thanks was passed from the chair to the Editors of the medical papers who so kindly from time to time, publish notices of the Society.

# The Medical Graduates College and Polyclinic.

THE Medical Graduates College and Polyclinic held their ninth annual dinner, under the Presidency of Prof. Howard Marsh, on Monday, 24th inst., at the Trocadero Restaurant. About 130 ladies and gentlemen assembled to do honour to the function. After the usual loyal toasts by the Chairman, he gave "The Medical Graduates' College and Polyclinic," able responses being made by Sir Jonathan Hutchinson and Dr. C. Theodore Williams. Dr. C. O. Hawthorne next, in a sympathetic discourse, proposed the health of Captain A. E. Hayward Pinch, I.M.S., and presented that gentleman with a cheque in recognition of the eminent services he had rendered the institution during ten years. Captain Pinch said a few words in response and thanks. "The Guests" were proposed by Dr. Dundas Grant, and responded for by Sir William Church, and the entertainment was brought to a close by the few admirable and apposite words of Sir Donald MacAlister in proposing the health of the Chairman. Not the least enjoyable portion of the evening was the clever and artistic entertainment at the piano given by Mr. Harrison Hill.

### Pirst Inquest Under the Children Act.

An inquest, the first held in the Isle of Wight under the Children Act, 1908, was conducted at the Cowes Town Hall by the Acting Coroner, Mr. J. Eldridge, on Tuesday of last week. Under the provisions of this Act it is compulsory upon any person who nurses and maintains for reward one or more children under seven years of age apart from their parents to report to the Guardians within 48 hours of their reception all particulars concerning such children, and the death of a child had to be notified to the Coroner within 24 hours and to the Guardians within 48 hours. In regard to the child whose death was inquired into, no notification had been made by the responsible person, Elizabeth Moth. The deceased's name was Gladys Vaughan; she was an illegitimate child, and was 11 months old. Witness had had care of it for ten months. The child was very delicate from the

first. When she became ill she was taken to Dr. Scott, who prescribed for her. The next day the child who prescribed for her. The next day the child seemed better, but on Friday afternoon it had a fit and died. Witness had had as many as 15 children

and died. Witness had had as many as 15 children to nurse, but did not know that she should have reported the particulars to the Guardians.

Dr. H. F. N. Scott said when brought to him on Wednesday the child looked ill, but he did not think it would die so suddenly. By direction of the Coroner he had made a post-mortem examination, and found that the internal conditions were consistent with found that the internal conditions were consistent with the child having died of convulsions. The child was well nourished, and there were no external marks of violence. So far as he could see, the child had been looked after well, but, having seen the child but once, he did not think he should have been justified in

giving a death certificate.

The Coroner, in summing up, referred to the provisions of the Act already given, and said the Guardians had appointed a special officer to inspect the children and their homes, and if they were not satisfied with the conditions they had power to remove the children. In regard to the case before them, Mrs. Moth had given her evidence very clearly, but she did not know that she should have registered the child when she took it in and reported its death to the Coroner.

A verdict of "Death from natural causes" was

returned.

### Royal Navy-Successful Medical Candidates.

At the Entrance Examination for Surgeons in the Royal Navy, completed on the 14th inst., 32 candidates presented themselves for 15 vacancies. Two gentlemen withdrew, eight were rejected for physical

gentlemen withdrew, eight were rejected for physical defects, and, of the remaining 22, 18 obtained qualifying marks. The following is the list of successful candidates, arranged in the order of merit:—

K. H. Hole, M.B., B.S. Lond., L.R.C.P., M.R.C.S., Guy's Hosp.; G. F. Syms, L.R.C.P., M.R.C.S., Guy's Hosp., Birmingham; M. P. Fitzgerald, M.B., B.Ch., R.U.I., Queen's College, Cork; J. Hadwen, M.B., B.S., B.Sc. Lond., L.R.C.P., M.R.C.S., St. Bartholomew's; H. F. Briggs, M.B., Ch.B.Edin., Edinburgh Univ.; G. A. Jackson, M.B., B.Ch., B.A.O., Dublin Univ.; W. Miller, M.B., Ch.B.Edin., Edinburgh Univ.; J. S. Orwin, M.B., Ch.B.Edin., Edinburgh Univ.; J. Sarrett, M.B., Ch.B.Edin., Edinburgh Univ.; J. Barrett, M.B., B.Ch., B.A.O., R.U.I., Catholic Univ., Dublin; H. W. Nichols, L.R.C.P., M.R.C.S., Middlesex Hosp.; R. P. M. Roberts, L.R.C.P., M.R.C.S., Guy's Hosp.; M. G. Malcolm, M.B., Ch.B.St.And., St. Andrews Univ.; H. C. Devas, L.R.C.P., M.R.C.S., St. Thomas's Hosp.; H. Burns, M.B., Ch.B.Edin., Edinburgh Univ. The above-named gentlemen will undergo a course of instruction in special subjects at Haslar Hospital.

The above-named gentlemen will undergo a course of instruction in special subjects at Haslar Hospital. on the completion of which another examination will be held, and prizes consisting of a gold medal, a silver medal, and three Navy regulation pocket cases awarded. The final position on the list will be determined by the combined results of the London and Haslar examinations.

# Royal College of Surgeons in Ireland. Pellewship Examination.

THE following candidates passed the Primary part of the Examination:—R. H. Barter, F. C. Crossle, J. L. Lunham B.Ch., P. M'Cartan, S. A. M'Swiney, and W. H. Condell.

The following passed the Final Examination and were admitted Fellows:—A. Chalmers, B.Ch., Captain I.M.S., J. H. Dauber, M.R.C.S., S. English, C.M., and T. H. Hay, C.M.

THIS week Shoreditch Borough Council received a this week Shoreditch Borough Council received a deputation from the newly-formed Public Welfare Council, a non-political and unsectarian body, urging the adoption of the Notification of Births Act and the appointment of a health visitor. Miss Böge, superintendent of the district nurses, and the Rev. E. R. Ford, Rural Dean, pointed out that Shoreditch has the highest infantile death-rate in the metropolis, and is one of the three London boroughs which have not one of the three London boroughs which have not adopted the Notification Act. The question was referred to the Public Health Committee for consideration.

# NOTICES TO CORRESPONDENTS. &c.

CORRESPONDENTS requiring a reply in this column are par-ticularly requested to make use of a Distinctive Signature or Instital, and to avoid the practice of signing themselves "Reader," "Subscriber," Old Subscriber," etc. Much con-fusion will be spared by attention to this rule.

#### SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Fereign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.02. Measrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £15s.; One-eighth, 19s. 6d.

The following reductions are made for a series:—Whole Page, £3 insertions, at £3 10s.; £6 at £3 3s.; £5 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, &c. —Seven lines or under (70 words), &s. 6d. per insertion; 6d. per line beyond.

Oniounal Articles on Letters intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

Ben Nevis.—We have no knowledge of the subject to which

BEN NEVIS.—We have no knowledge of the subject to which our correspondent refers.

RESPICE FINEM.—The cost of radium is prohibitive, save to wealthy patients. Possibly any large retail chemist would quote a price for the quantity required.

TUBERCULOSIS IN IRELAND.

LADY ABERDEEN stated recently at the opening ceremony of a tuberculosis exhibition that she had received a letter from Sir Robert Matheson, Registrar-General for Ireland, in which he stated that the mortality rate from all forms of tubercular disease in 1808 was down by one decimal point. In every one of the three years 1905, 1906, and 1907 the rate per thousand of the population was 2.7, whereas last year it had fallen to 2.5 per thousand.

MR C H S One of the Table 1907.

of the three years 1905, 1906, and 1907 the rate per thousand of the population was 2.7, whereas last year it had fallen to 2.5 per thousand.

Mr. C. H. S.—One of the most abominable frauds, it would not be wise for us to "efer to it, as the proprietors would probably quote this journs" as having recommended it, without mentioning our strong condemnation. The medical man they refer to as an authority in the subject does not exist, at least we cannot find his name in the published list.

Dr. Statt Dutton.—Your paper is marked for early insertion, proof will be sent you in due course.

A Young Qualified Member.—Dr. W. G. Dickinson, West Hill, Pulney Heath, S.W. is the Hon. Secretary of the Society of Members of the Royal College of Surgeons, England. A letter addressed to him would enable our correspondent to learn all the information he required.

Mr. Lloth George has stated that medical men will not be entitled to rebate of duty on the petrol used in their cars. The cides, we believe, it, that they will be more than compensated by the number of persons who will get ill from financial worry brought on by the Budget.—Punch.

G. De G.—It is fairly common for a single microbe to produce multiple lesions of a most diverse nature—e.g., the pneumococcus, which, apart from the lung, may produce joint lesions, abscesses in any part of the body, and even ulcerative endocarditis. Another good example is afforded by the gonococcus which may produce joint affections, acute and chronic, in an extraordinary variety. In estimating the action of any given microbe, however, it is necessary to exclude the fallacy of a mixed infection. A most interesting and suggestive observation on this connection is the large number of different micro-organisms that have been found in ulcerative endocarditis. We believe the pneumococcus is often found in the lackrymal ducts, sometimes in purulent conditions.

# Meetings of the Societies, Tectures, &c.

WEDVESDAY, MAY 25TH.

MEDICAL GRADUATES COLLEGE AND POLYCLINIC (22 Chemies Street, W.C.).—4 p.m.: Mr. R. Johnson: Clinique (Surgical). 5.15 p.m.: Lecture: Dr. R. W. Allem: The Pathology and Treatment of a Common Cold.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—Clinics: 2.30 p.m.: Medical Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meschen); Eye (Mr. R. P. Brooks).

THURSDAY, MAY 27TH.

MEDICAL GRADUATES COLLEGE AND POLYCLINIC (22 Chemies Street, W.C.).—4 p.m.: Sir Jonathan Hutchinson: Clinique (Surgical). 5.15 p.m.: Lecture: Sir John Broadbent, Bart.: Relation of Arterio-Scleroeis to Aneurysm and Renal Disease.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynseological Operations (Dr. A. E. Giles). Clinics: Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. H. W. Carson); X-Rays.

5 p.m.: Medical In-patient (Dr. G. P. Chappel).
Lecture: Mr. H. W. Carson Catarrhal Deafness.

ROYAL SOCIETY OF MEDICINE (SECTION FOR THE STUDY OF

ROYAL SOCIETY OF MEDICINE (SECTION FOR THE STUDY OF DISSASE IN CRILDREN) (20 Hanover Square, W.).—4.30 p.m.: Papers: Dr. Parkes Weber: Congenital Obliteration of the Bileducts with Cirrhosis. Mr. A. R. Thompson: Congenital Dislocation of Hip. Cases: Dr. Eric Pritchard: (1) Unilateral Hypertrophy of the Hand; (2) Symmetrical Helioal Fistulæ with Branchial Fistula in an Infant. Mr. Sydney Stephenson: A Case of Oxycephaly. Dr. George Carpenter: (1) Case of Congenital Morbus Cordis; (2) Specimen of Congenital Hypertrophic Stenosis of Pylorus. And other Cases.

CENTRAL LONDON THROAT AND EAB HOSFITAL (Gray's Inn Road, W.C.).—3.45 p.m.: Lecture: Mr. W. Wallis: Mouth and Teeth.

# Appointments.

BAZALGETTE, STDNET, L.R.C.P.Lond., M.R.C.S. First Assistant Medical Officer at the Bristol City and County Asylum,

BAZALGERTE, STENEY, L.R.C.P.Lond., M.R.C.S. First Assistant Medical Officer at the Bristol City and County Asylum, Fishponds.

Byrrs, G., M.B., M.S.Aberd., Medical Officer to the Aberdeen City Parish Council.

Fairmann, H. A. T., M.S.Lond., F.R.C.S.Eng., Surgeon to the Miller General Hospital for South-East London.

GILBERTSON, A. J., M.B., B.S.Durh., Honorary Surgeon to the Monkwearmouth and Southwick Hospital, Sunderland.

Jones, Jehn Ellington, L.R.C.P.Lond., M.B.C.S., L.S.A., Honorary Skiagraphist to the Orthopsedic Hospital for Crippled Children, Redland, Bristol.

MINCHIN, P. Dundas, L.R.C.P. and S.Edin., L.F.P.S.Glasg., Medical Officer and Public Vaccinator for the Etwall Diatrict of the Burton Union.

MORTON, WILLIAM BRITAIN, M.D.Lond., L.B.C.P.Lond., M.R.C.S., Medical Superintendent at the Wonford House Hospital for the Insane, Exeter.

NEWALL, W. A., M.D., Ch.B., D.P.H.Vict., Honorary Assistant Physician to the Chester General Infirmary.

PHILLIPS, JORN ROBERT PARRY, L.R.C.P.Lond., M.R.C.S., Junior Medical Officer at the Bristol City and County Asylum, Fishponds.

Revie, A., M.S., M.S.Glasg., Visiting Surgeon to the Kilmarnock Infectious Diseases Hospital, Exeter.

## Vacancies.

DALAILLES.

Abertillery Urban District Council.—Medical Officer of Health.
Salary, £350 per annum. Applications to William Gait. Clerk
to the Council, Council Offices, Abertillery.

King Edward VII. Sanatorium, Midhurst, Sussex.—Senior Assitant Medical Officer. Salary, £150 per annum, with board,
lodging, and attendance. Applications to the Hen. Sewestary,
19 Devonshire Street, Portland Place, London, W.

State of Western Australia Medical and Health Department.—
Medical Officer to the Central Board of Health. Salary, £400
per annum. Applications to James W. Hope, F.R.C.P.,
R.C.P.S.I., etc., Principal Medical Officer, Perth, Western
Australia.

Suffolk District Asylum, Melton.—Second Assistant Medical

Australia.

Suffolk District Asylum, Melton.—Second Assistant Medical Officer. Salary, £160 per annum, with board, furnished apartments, attendance, and laundry. Applications to the Medical Superintendent.

Darenth Asylum.—Mals Third Assistant Medical Officer. Salary, £150 per annum, with rations, lodging, attendance, and washing. Applications to the Superintendent, Darenth Asylum. Dartford, Kent.

West Norfolk and Lynn Hospital, King's Lynn.—House Surgeon. Salary, £100 per snnum, with board, residence, and washing. Applications to the Chairman of the Weekly Board.

Wye House, Buxton.—Assistant Medical Officer. Salary, £120 per annum. Applications to the Medical Officer.

# Births.

Howitz.—On May 19th, at "Lyme Regis," Hough Green, Chester the wife of J. H. Howitt, M.A., LL.B., M.R.C.S., L.R.C.P.,

MURISON.—On May 19th, at Burleigh Lodge, Erith, Kent, the wife of W. R. Murison, L.R.C.P., and S. Edin., of a daughter.

# , Beaths.

DRINKWATER.—On May 19th, at St. John's, Bicester, Orea, suddenly, William Drinkwater, M.R.C.S.Eng., L.R.C.P.Edin., aged 66.

HULL.—On May 19th, at Highfield, Rournementh, Hamiltonian

aged 68.

HULL.—On May 18th, at Highfield. Bournemouth. Harriette, daughter of the late Thomas Hull, M.D., of Boverley, Yorkshire, aged 89.

James.—On May 17th, Captain Henry Charles Melville Northage James, 98th Int., I.A., only and most dearly loved son of the late Dr. H. N. L. James, M.D., A.M.D., and Janie E. B. James, of synoope after swimming, near Swahage, aged 34.

Kebell, of Brisbane, Queenaland.

Kempell.—On May 18th, auddenly, Eatherine Agnes Kebbell of 26 Carlyle Square, S.W., widow of the late Dr. William Kebbell, of Brisbane, Queenaland.

Kempel.—On May 23rd, in his 70th year, Charles Marshall Kempe.

M.R.C.S., L.S.A., of New Shoreham, Sussex, after a short illness Miller.—On May 18th, at 33 Tavistook Square, Bloomsbury, Archie Ferguson Miller, M.B. Ch.B.Edin., only son (4 Melville and Sarah Miller, of Leievre Terrace, Adelaide. South Australia, aged 26.

# Antiphlogistine

(Inflammation's Antidote).

Applied from ear to ear as hot as can be borne comfortably by the patient, depletes the enlarged lymph glands, guards against the passage of toxines into the circulation and reduces the liability of Mastoiditis, Middle Ear and Laryngeal complications in Tonsillitis,

Scarlatina, and other diseases of similar nature.

The dressing of Antiphlogistine must be at least an eighth of an inch thick, covered with a plentiful amount of absorbent cotton and held snugly in place by a bandage.

# The Valuable Properties "Lactonised" Milk.

Herter considers that putrefactive intestinal processes may be favourably influenced by fermented milk containing an abundance of lactic acid and lactic acid organisms.—Brit. Med. Journ., Dec. 25, 1907.

Metchnikoff states that some forms of lacticacid-producing miero-organisms inhibit the growth of certain pathogenic and putrefactive bacteria.—Medical Annual, 1908, p. 212. Emerson reports that lactic acid promotes peptic secretion and digestion, and that milk which has undergone lactic acid fermentation is a valuable food for infants and invalids in digestive disorders, especially those of a fermentative character, also in the dietary treatment of pulmonary tuberculosis and in the modified food of healthy infants.—New York Med. Journ., Feb. 8, 1908.

# LACTONE TABLETS (P., D. & Co.)

furnish a pure culture of lactic-acid bacilli in an active state and in a form convenient for fermenting fresh milk. The product closely resembles in taste and appearance buttermilk fresh from the churn, but is safer, since the latter is liable to be contaminated with putrefactive bacteria and alcohol-producing yeasts, and is more nutritious, since it contains all the butter fat.

"LACTONISED" MILK forms a wholesome food which is particularly useful in cases of gastric ulcer, chronic gastritis, typhoid fever, acute diarrhœa, malnutrition, etc. Reports state that it is excellent for infants, being easily borne and apparently inhibitive of intestinal disorders. If it proves too rich, it may be prepared from skimmed milk instead of whole milk.

Christinson states that milk treated with Lactone Tablets (P., D. & Co.) produced remarkable improvement in weight and general condition in 108 cases of gastric disorders in infants from 8 weeks to 9 months old; also in inoperable cancer of adults, in gastritis and indigestion. When so indicated, he modified it by diluting with barley, oatmeal or rice water, or by the addition of sugar.—St. Paul Med. Journ., July, 1907.

Lactone Tablets (P., D. & Co.) are supplied in bottles of 25.

# Notes and Comments.

THE L.C.C. Committee have no doubt as to the crucial question of Who is to Call in · whose duty it is to call in medical the Doctor? relief for the defects discovered by the inspection. They have stated in so many words that "the responsibility for consulting a doctor is to be thrown upon the parents, and the Council purposes to disclaim all responsibility for the treatment prescribed or given." Now it seems to us that inspection without treatment is very much like notification of fevers without disinfection—that is to say, the primary step is rendered nugatory and worthless. A London physician not long ago related to the present writer a personal experience bearing upon the point in a village in his native county. A coachman told how one of his children had been sent back from the medical inspection with the advice that seven teeth should be drawn, adenoids removed, and glasses obtained for an error of eyesight. The man appealed to the physician for advice in so grave a domestic catastrophe, but as a matter of fact he obtained but scant comfort. This instance is by no means extreme. It represents a state of affairs in which a huge expenditure of public money may be practically thrown away, and an Act that is full of splendid potentialities reduced to the level of a laughing stock. Had the Government taken the medical profession into their confidence before adopting the measure, it is not unlikely that a good deal of the difficulty would have been avoided. In any case, some decision should be arrived at by the London County Council before long. The matter is complicated, but there should be no insuperable obstacle in the path to prevent a wise and just decision as to the best course to pursue. We hope before long to place a definite policy before our readers for discussion, and, meantime, we shall be pleased to hear any suggestions.

MEDICAL terminology is a standing source of wonderment and not a Fine Feathers little bewilderment to the uninitiated, and perhaps in these days, when everybody takes such a keen interest in medical matters, it is just as well that the profession should keep inviolate the sacred tradition, which in the past sufficed to cover a vast amount of clinical nescience. Moreover, those who strive to pierce the arcana of our science are not a little pleased with themselves when they are able to use the word epistaxis for

nose-bleeding, or to speak of cuticular abrasion when they mean a scratch. A considerable discussion took place at a recent trial in the High Court over the proper pronunciation of the word tinnitus, and the learned judge was quite flattered at having the pleasure of deciding that the classical usage demanded that that second "i" should be kept long. Such points, however, are refinements which, as a rule, do not trouble the profession much, and the laity who seek to imitate our speech even less. To this day the pronunciation of the word "enema" is almost as variable as a woman's whim, in spite of classical precedent and the common usage of the language. But we cannot say we admire the habit which has sprung up, especially in America, of compounding an amorphous pseudo-classical product to describe every variety of symptom and every phase of disease.

make castle Chron

Our contemporary, the Newcastle Chronicle, is much perturbed at the way in which medical terminology is getting beyond the

ken of plain paths, and we are bound to admit that if the examples they set forth can be described as that recognised by the profession generally, we ourselves are equally at a loss. The worst part of the case is that the alarming words are used to connote diseases which we should hesitate to class as morbid conditions, as otherwise we should find mankind little else than a pathological specimen. For instance we are told that "modern science declares this habit of compressing the eyebrows (in frowning) to be a nervous disorder, and baptises it 'synophriomania.'" Well, that certainly is enough to keep a man from scowling for the rest of his days. Then we learn that a person who bites his nails is afflicted with "onyxophagia," a word which strikes us as being as badly constructed etymologically as it is unnecessarily pedantic. The encouragement meted out to the meticulous in the phrase "Pull up your socks," should, we gather, be withheld lest the object of solicitude become a "kratopodomaniac," and Ouida's guardsmen who used to tug at their long moustaches at every crisis in their career should in the modern novel, be made to adopt some other gesture of perplexity, lest they be classified by the instructed as "mistakostrepsomaniacs." Lest we unduly cause alarm to those afflicted with habit spasm and other minor nervous derangements, we will not prolong the list.

Quack

ONE of the methods of the modern quack, after his advertisements Developments. have enticed a reply from a victim, is to keep "rubbing it in" to him if he does not bite as long

and as hard as the wily angler desires. Each week or two produces a freshly-worded letter reminding the hesitating one of the dangers of delay, and of the certainty of salvation by the advertised nostrum. Truth has just published a specimen of this method, which shocking or amusing, according to whether the matter is viewed philosophically or cynically. The firm cited by them is the "Dr. Van Vleck Co.," of Shoe Lane, E.C., and the fourth "follow up" begins with the question—"Do you realise that every month's delay is bringing you present the correction the bringing you nearer the operation table, or to a fatal termination of your disease?" and later it adds: "Are you annoyed at our writing to you?" "Annoyance," writes our contemporary, seems to be a quite inadequate term to express the feeling of the recipient of such an outrageous attempt to scare him into parting with half-a-guinea." We think so too. The callous and heartless indifference to every consideration, except that of obtaining an order, is revolting.

The Girl and the Curi.

RECENTLY there has been one of the periodical outbursts of malignant opposition to methods of medical advance on the part of the "anti" sections of society,

which took the peculiar form of denouncing the X-ray treatment of ringworm on the ground that, although the ringworm was cured, the patient's mental capacity was seriously stunted by the permeation of the brain by the rays. Of that we can only say that we are sure that X or any other kind of rays could have but little effect in dwarfing the intellectual development of the gentleman who made the outcry. As an off-set to this devastating influence of the rays, the Chairman of the Education Committee of the London County Council has come forward as an advocate of the treatment on the ground that the rays transform hair of the rat tail variety into curly locks of the most amatory description. Without posing as the possessors of special knowledge of the question, we may safely assert that among the young adults, at any rate, the popularity of Professor Röntgen is likely to advance by leaps and bounds if there is any truth in the assertion. The fact (if fact it be) that the brain is damaged would, among the jeunesse dore weigh lightly in the balance with the equally hypothetical fact that love-locks and kiss-curls followed the application of X-rays to the scalp. It is unfortunate that a necessary precedent condition to the appearance of these amorous stigmata should be complete depilation, but a rest cure " or a holiday abroad might be insisted upon by the beauty-culturist to tide over the period of baldness. From knowledge of the excesses to which human nature will advance in the cult of personal attractiveness, we have little doubt that the chin-straps "stuffed with fragrant herbs," and face-creams, and "skinfoods" would have little chance against any agent which would really cause Anglo-Saxon locks to assume the tortuous sinuosity of those of the sons of Ham.

# LEADING ARTICLES.

THE DIAGNOSIS OF UTERINE CANCER.

Or all problems that face medical investigation and medical treatment, there is none more difficult than that of cancer. In spite of the huge amount of skilled scientific labour that is being lavished upon the subject in many parts of the world, the ætiology appears to be little less obscure and the treatment little less hopeless than it was a generation ago. Now and then a gleam of light appears to break through the darkness, as happened, for example, when the definite influence of the X-ray tube upon recurrent nodules after operation was noted. Another encouraging fact is the influence of radium upon certain growths, and last, but not least, the complex action of ferments from internal organs as regards new growths. The greatest advance hitherto made in the campaign against cancer has undoubtedly been the recognition of the fact that early and free operative removal affords the best chance of recovery. That statement, indeed, sums up the situation so far as prognosis is concerned. The chances of a favourable issue depend, for all practical purposes, upon early operation, and that, again, upon early recognition. With regard to diagnosis in the first stages, it is often extremely difficult to recognise the condition. especially when it attacks internal organs, such as the stomach or uterus. At the same time there are various signs and symptoms, both general and local, which, taken in conjunction with the age and appearance of the patient, often warrant the surgeon to make an exploratory incision, although in themselves insufficient to justify a decided opinion as to the nature of the condition. In the case of uterine malignant growths it is a constant experience of hospital surgeons and gynæcologists that the disease has not been detected until too late for operative interference. In this way a number of valuable lives are constantly being lost, a fact that had long engaged the attention of the gynæcological societies, and, on the recommendation of the Obstetric Section, at the annual meetings, 1907 and 1908, of the British Medical Association, the matter was referred to a Special Committee for report. Under the able chairmanship of Dr. F. J. McCann, the Committee has submitted a full and exhaustive report, which has been since approved by the Council. This most important document was published in The Medical Press and Circular for May 12th, deserves the widest publicity amongst the classes who are chiefly brought into contact with uterine cancer in its early and curable stages, namely, medical practitioners, nurses and midwives. As a matter of fact, the Special Committee state that three-fourths of the uterine cancer cases that come under the care of the gynæcologists have previously been in the hands of their private medical attendants, who in not a few cases have undertaken treatment without local examination. The great source of danger, however, lies in what is aptly termed the "folklore of the menopause." Irregular bleeding about the period of life, associated with the cessation of menses, is treated lightly as "change of life," whereas it may, and often does point to conditions of the gravest kind. It is only by educating womankind generally, and nurses in

particular, as to the necessity of immediate skilled attention under such circumstances that any reasonable amount of security against the scourge of uterine cancer may be anticipated for coming generations. Should Dr. McCann's committee achieve nothing beyond the national advertisement of the risks of irregular uterine bleeding in middle life, she will have done a practical service to the community of which it is impossible to speak too highly. For the appeal to nurses and midwives they have issued a short and direct appeal, setting forth in simple language the facts of the case, and winding up with the following appreciation: - "The nurse or midwife who is told by a patient that she has any of these symptoms should insist upon her seeing a medical practitioner, in order that an examination may be made without delay. By doing so they will often help to save a valuable life, and will bring credit to herself and her calling." appeal to medical practitioners contains a clear detailed account of the symptomatology, methods of examination, forms of uterine cancer, microscopical examination, and operation. As this important document has already appeared in our columns, there will be no need to discuss it at length. It may be well, however, to reiterate the statement, made with all the weight of responsible and skilled authority, to the effect that, "probably the majority of cancer cases which are overlooked are examples of disease affecting the lining of the cervical canal or the tissues of the wall of the cervix." To this may be added the final recapitulation, which runs:—"(1) Attend to all symptoms suspicious of cancer, and instruct the patient on their importance; (2) examine immediately all cases of bleeding or abnormal discharge; (3) make a definite diagnosis, and do not wait for disease to develop; (4) urge immediate operation if the diagnosis be established. The practitioner who diagnoses cancer in an early stage, while operation affords probability of cure, renders a service to his patient as great as that rendered by the operator." This document should be carefully laid to heart and preserved for future reference by every practitioner who is likely to be brought into contact, directly or indirectly, with the class of cases referred to. It is to be hoped that the labours of the Committee will be rewarded by a future lessening of one of the constantly recurring but preventable tragedies of human life.

# CURRENT, TOPICS.

The L.C.C. and Voluntary Medical Fervice.

The proposal of the Education Committee of the London County Council to make use of the voluntary medical charities of the metropolis for the treatment of school children opens up issues of vital importance to medical practitioners throughout the Kingdom. Even though adequate fees for such treatment be paid to hospitals and dispensaries, it is clear that the charities would be making money out of the gratuitous services of the honorary staff, which are placed at the service of the poor and suffering, but not to be "sweated"—if we may use that term—for the convenience of charitable institutions and of public administrative bodies.

The resulting economic wrongs of the proposal, however, extend far beyond the mere trespass on the good nature of honorary staffs. There is the further fact often emphasised in these columns, namely, that the making of money by trading hospital organisation is to subvert trust funds subscribed for the clearly-defined purpose of relieving the sick poor. Finally, there is the unfair competition with outside general practitioners involved in the payment of fees to the hospitals or dispensaries. The mere amount of the fee does not lessen the injustice of the transaction; indeed, the larger the sum paid the greater the injury to the outside medical demand, from whose legitimate income the fee may in many, if not in all, cases be said to have been abstracted. We are glad to see that the Metropolitan Counties Branch Council of the British Medical Association has considered this important subject, and has issued a circular letter to London members. that document the situation is clearly discussed. The collective action of the profession is invited as follows:—"In the absence of the proper appointment of school medical officers, the Branch Council (in view of the foregoing considerations) is of opinion that the members of the staffs of the hospitals in London should unanimously oppose the project of the County Council." It is encouraging to find that the profession is taking steps to circulate conclusions whereby medical men may be guided in a wise line of conduct as regards their relations with public authorities, not to mention the defence of their own interests.

### An American Plan of Campaign against luberculosis.

AMERICA is the home of new ideas, and it is encouraging to find that they are not always confined to the problem of extracting the greatest amount of money from the national and international environment and resources. The fight against tuberculosis, for example, is conducted with continuous and unabated vigour. The great city of Chicago recently, by referendum, sanctioned the levy of a tax for the purpose of erecting and maintaining a sanatorium for consumptives, and Governor Hughes has just signed Bills authorising New York City and the counties of the State to establish similar hospitals. The number of cases reported during the last two years shows an apparent increase, but this the Health Commissioner attributes to earlier and more complete registration. The imposition of a general tax for the specific purpose of fighting tuberculosis is a principle that deserves careful attention by the British Government. From an economic point of view it seems reasonably certain that the gain to the national wealth would in the long run far more than repay the outlay. It would be interesting to have the considered opinion of an economist like Mr. Chiozza Money on so important a point.

# A Medical Centenary.

Among the many distinguished men the centenary of whose birth is being celebrated this year, one of special interest to our profession is Oliver Wendell Holmes. Though most of his fame is due to accomplishments in other than medical fields, it is not to be forgotten that Holmes was for many years an active member of the profession, and was always

proud of his connection with it. In a manner, his literary success left science the poorer, for there can be little doubt that had Holmes continued to work at scientific subjects in the spirit manifested by his early essays, he would have given the world contributions of importance. Of his medical achievements, his essay on the cause of puerperal fever is, of course, the most important, by reason of the remarkable prescience and courage which Holmes showed as a pioneer. His work "for the poor women" was always a source of wholesome pride to him, and it is curious now to look back to the bitter opposition shown towards his modest and unassailable conclusions by such conservatives as Hodge and Meigs. Holmes' fame as the discoverer of the nature of puerperal fever is somewhat overshadowed by that of Semmelweis, who reinforced Holmes' cogent reasonings by experimental proofs, but Holmes' labours must not be despised.

### Phthisis and Dust.

At the inquiry recently held at Sheffield by Mr. A. H. Lush, on behalf of the Secretary of State, to determine on the practicability and acceptability of new regulations for the grinding trades, the Home Office view was put forward by counsel, Mr. S. Pope, and medical witnesses, whilst various confederations of employers were represented on the other side. The figures mentioned by Mr. Pope were eloquent of the danger of respiratory diseases among grinders. Quoting from Dr. Sinclair White, he showed that whilst per 1,000 deaths among the male population, 144 were due to phthisis and 182 from other respiratory diseases, the mortality figures for grinders under the same heads were 345 and 295 respectively. Moreover, from the same source of information he announced that whereas 261 of the male population died between the ages of 35 and 55, and 391 after 64, amongst I grinders the numbers were 458 between 35 and 55, and only 140 after 64. Dr. Scurfield had shown that the phthisis rate among grinders was three times as great as that among the average male population of Sheffield, and from other respiratory diseases four times as great. After Mr. Pope had commented on the satisfactory spirit that had been shown by both masters and men in the consideration of the regulations, Colonel Hughes, who appeared for several large employers' associations, said that he advocated regulation, but feared that the proposed safeguards might hamper trade without having beneficial effects. Now the influence of the dust is the important factor—that is to say, that without dust phthisis need be no more common among grinders than among any other class of the community. But given dust, and irritation of the lung by its agency, inflammatory processes are set up which readily yield themselves as prey to so widely-spread an infection as that of tuberculosis. The dust generated in grinding processes consists of hard, sharp spicules, and, consequently, damages the lung far more than soft dust, like that of coal, and to this fact is due the enormous mortality of grinders. The indiscriminate spitting of workers should no doubt be stopped, and if tuberculous men are employed in these processes at all, which we should judge to be highly unwise for their own sakes, they should be supplied with spitting flasks or similar hygienic receptacles. But we hope the Home Office will not be drawn away from the question of dust by undue fear of infection.

# "Wireless" Surgery.

Ar a recent meeting of the Royal Institution of Great Britain Dr. Horace Manders showed a new method of dealing with warts, rodent ulcers birth marks and superficial epitheliomata. The apparatus, briefly described, consists of an ordinary scalpel, the blade of which is connected with a storage battery. The current, however, by a special device invented by Dr. Manders, is converted into a continuously maintained series of oscillations similar to those used in certain systems of wireless telegraphy. The application of this knife to the tissues combines the cutting with a cauterising action. This electro-cutting process, however, differs from the ordinary thermo-electric cautery in that there is less shock and no tendency to subsequent hæmorrhage. One interesting feature about the method is that the cauterising action is confined to an area represented by a fraction of a millimetre outside the surface of the knife, which remains cool throughout the operation. This new departure should prove of service for various surgical purposes, and it serves to remind us that the applications of modern electric methods are by no mean exhausted. During the past generation, for instance, quite a number of valuable electrical appliances have been introduced into the practice of medicine and surgery.

# "Wireless" Prescriptions.

THERE are still plenty of people living who can remember the sensation caused when the famous Windsor murderer was arrested when he arrived at Paddington Station, by reason of his departure in the train being communicated to the metropolitan police by means of what was then known as the "electric telegraph." In those days the occurrence caused as great a sensation as an arrest by eroplane or Zeppelin would create now. The Daily Telegraph has brought to light a story, if not as exciting, at any rate, so far as our knowledge goes, as dramatic in its details. This is no less than the recovery of a lady in Philadelphia by means of a prescription sent by "wireless" by her own physician in New York. The lady in question was a wealthy American, by name Mrs. Felman, and apparently preferring the ministrations of her accustomed attendant to those of a new doctor, when taken ill she "wired" to her medical man, who was crossing the Atlantic. for his advice. The latter sent back a message containing a prescription which had a wonderful restorative effect, and as the whole performance only cost ten dollars, the patient probably saved money on the transaction. The extension of the

radius and responsibilities of practice which this incident suggests are rather alarming. Hitherto the medical man has thought that he can at least be free from the troubling of the wicked by going down to the sea in ships, but now even that solatium is likely to be denied him. If consultation by Marconigram is to become at all common, it seems probable that suicide will offer the only effective alternative to being continually at the beck and call of wealthy neurotics.

The Orange Sanguineous.

WE are not sure as to what may be the attractiveness of the blood-orange, but the fact remains that that variety of the fruit possesses a great fascination for many buyers. The colour red has a quality that charms the eye in a peculiar manner, so that there is a general notion that red wine is "richer" and more nutritious than sherry or sauterne. Cunning advertisers are apt to extol the merits of inferior red wines on the ground that they are "blood-making" (whatever that may mean), and the analogy between the tint of hæmoglobin and that of claret or burgundy appeals irresistibly to the popular imagination. The same principle seems to apply in the case of the blood-orange, which is accounted more luscious than its less pretentious and more common-place brother. In this connection our contemporary, La Presse Medicale, has brought to light a curious trade trick which was brought to its notice by an unusual accident. In St. Petersburg recently a girl who had eaten a blood-orange was shortly afterwards taken with acute pain in the throat, accompanied with hæmoptysis. When examined medically it was found that she had a piece of a Pravaz needle imbedded in the pharynx, which in due course was safely removed. The connection between the blood-orange and the Pravaz needle was not at first sight clear, and the medical man pursued his inquiries till he traced the street-seller from whom the oranges were bought. When squarely tackled the man admitted that he was in the habit of injecting ordinary oranges with a solution of aniline dye by means of a Pravaz needle in order to palm them off on the unwary as blood-oranges. The secret was then out. For the sake of commercial integrity and the salubrity of the pharynx one can only trust that this custom will not invade our own shores.

# PERSONAL.

HIS ROYAL HIGHNESS THE PRINCE OF WALES, HIS KOYAL HIGHNESS THE PRINCE OF WALES, accompanied by the Princess, presided over the inaugural meeting of the Seventh International Cengress of Applied Chemistry at the Albert Hall on the 27th May last. Their Royal Highnesses were received by Sir Henry Roscoe, the honorary President of the Congress, and Sir William Ramsay, the President.

LORD GRENFELL presided on May 25th at the annual LORD GRENFELL presided on May 25th at the annual meeting of the Invalid Children's Aid Association, held at 16, Grosvenor Place, by permission of Lord Newlands Among those present were Sir Charles and Lady Fremantle, Lady Broadbent, Sir Alfred and Lady Fripp. and Mr. Warrington Haward.

PRINCESS ALEXANDER OF TECK was present on May 25th at No. 3 Grosvenor Place, lent for the occasion by Lady Esther Smith, at the sixth annual meeting of the Rural Midwives' Association, and distributed good the Rural Midwives' Association, and distributed good service certificates to a number of nurses on the conclusion of their term of service. Mr. Almeric FitzRoy, C.V.O., chairman of the Departmental Committee on the Midwives Act, presided.

THE Council for the Promotion of the Higher Training of Midwives held its annual meeting at The Deanery, St. Paul's, on May 25th, when the chair was taken by Lady George Hamilton.

THE forty-first annual meeting of the Queen's Hospital for Children, Hackney Road, was held at the hospital on May 24th, under the chairmanship of Lord William Cecil.

Dr. WILLIAM ENGELMANN, the distinguished Professor of Physiology in the University of Berlin, died on May 20th, at Berlin, at the age of sixty-five. Professor Engelmann was professor at Utrecht before his removal to Berlin.

THE National Hospital for the Paralysed and Epileptic (Albany Memorial), Queen Square, Bloomsbury, W.C., celebrates its jubilee this year, and will hold a festival dinner, with the Right Hon. the Lord Mayor in the chair, on June 10th, at the Mansion House.

The National Society for the Pievention of Cruelty to Children (by Royal Charter) held a great meeting in the Mansion House, London, on Monday, May 24th, when the Right Hon. the Lord Mayor presided, and the speakers included the Earl of Ancaster, Lord Alverstone (Lord Chief Justice of England), the Right Hon. Herbert Samuel, M.P., Sir Francis Channing, Bart., M.P., the Bishop of Kensington, and the Rev. Father Bernard Vaughan, S.J.

THE opening ceremony of the Berlin Tuberculosis Congress took place in that city on May 22nd, when Dr. von Bethmann-Hollweg, Imperial Secretary of State for the Interior, delivered the Inaugural Oration, describing the growth and development of institutions for experimental research in connection with tuber-

A CONFERENCE arranged by the Invalid Children's Aid Association will be held on June 22nd and 23rd. At the four sessions of the conference the chair will be taken successively by the Duchess of Sutherland, Lord Aberdeen, Dr. Arthur Latham, and Mr. Loch. All information can be obtained of the Secretary, Invalid Children's Aid Association, 69, Denison House, 296, Vauxhall Bridge Road, Westminster, S.W.

Mr. HOWARD MARSH, M.C., F.R.C.S., Professor of Surgery in the University of Cambridge and the Surgery in the University of Campriage and the Master of Downing College, presided at the annual dinner of the Medical Graduates' College and Polyclinic at the Trocadero Restaurant. Among those present were Sir W. Church, Sir D. MacAlister, Sir Y. MacAlister, Sir M. MacAlister, M J. Hutchinson, Sir A. H. Keogh, Inspector-General J. Porter, Mr. Bland Sutton, the Master of the Society of Apothecaries, Dr. Fletcher Little, Dr. Theodore Williams, Dr. A. Newsholme, and Dr. T. N. Kelynack.

Ar the forthcoming annual election to the Council of the Royal College of Surgeons the members who retire by rotation are: Mr. A. W. Mayo Robson, Sir W. Watson Cheyne, and Mr. R. Clement Lucas. It is understand that Mr. Harrison Cripps and Mr. W. W. H. Jessop, senior surgeon and senior ophthalmic surgeon respectively at St. Bartholomew's Hospital, are intending candidates for election. The requisite forms to be filled up by Fellows of the College who are desirous of standing for election must be delivered at the College not later than June 4. AT the forthcoming annual election to the Council

# A CLINICAL LECTURE

ON

# THE CLINICAL FORMS OF ARTERIO. SCLEROSIS.

By PROFESSOR H. HUCHARD, M.D.,

Of the Faculty of Medicine of Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

Although the question of arterio-sclerosis has been under discussion for the last forty years, it is still far from settled, as has been shown by various recent contributions. This is because it is one of the questions that are not based on any exact definition on which observers can come to an agreement. If, as I suggested, there are few contradictory data but many contradictors, this may be ascribed to the fact that some observers regard arterio-sclerosis merely as an anatomical lesion, and do not pay the clinical evolution the attention it deserves.

To hold that the disease is constitutional and at the same time that it is limited to the smaller blood-vessels, or to admit that it invariably commences by endarteritis or mesarteritis, is both to unduly narrow and also to unduly enlarge its scope. To confuse it with atheroma is to take the lesion for the disease. Then, too, to maintain that we may hope to learn the pathogenesis of arterio-sclerosis by experiments with agents that heighten arterial tension is to ignore the fact that hyper-tension is in no wise a necessary accompaniment of arterio-sclerosis, overlooking the fact that we meet with cases of arterio-sclerosis which run their course with a lowered tension (intestinal arterio-sclerosis).

To assert on the other hand that arteriosclerosis is under the dependence of the nervous system, in other words, a tropho-neurosis, appears to me to be begging the question by mixing up the pathogenesis with the ætiology.

Let us turn now to hypertension, which is so often invoked as a cause of arterio-sclerosis. Whatever its importance may be it is far from being the primum movens of arterio-sclerosis in the sense of being directly a consequence of the intoxication, and therefore the underlying influence in determining the clinical course of the disease. Arterial cardiopathies commence with intoxication, they continue with intoxication, and they end with intoxication. Without overlooking the manifold and grave dangers associated with hypertension, I hold that it does not explain the whole symptomatology of arterio-sclerosis in which the disturbances due to the intoxication, along with the cardiopathy, are the principal factors. When hypertension is consequent upon intoxication, the latter is usually of alimentary origin, no better proof whereof is necessary than the toxic dyspnœa, the predominant symptom in arterial cardiopathies, which disappears so readily on milk, or even lacto-vegetarian diet.

With reference to the cases of arterio-sclerosis which run their course in hypotension it appears to me that the disease is consequent upon what, seven years ago, I called "portal hypertension." These patients suffer from "abdominal plethora" with enlarged liver, are liable to recurrent pulmonary congestion and have a readily dilatable heart. The damaged liver no longer

fulfils its antitoxic function, so that toxic substances find their way into the circulation and irritate the walls of the vessels. This stasis and portal hypertension are amenable to abdominal massage which yields excellent results.

On the strength of Josué's experiments, sundry observers have tried to show that arterio-sclerosis is of suprarenal origin, but my own view is that experiments cannot possibly afford us an explanation of the pathogenesis of arterio-sclerosis, for the simple reason that although we may succeed in determining an arterial lesion, we cannot reproduce a disease with all its sequelæ. To set up generalised arterio-sclerosis in an animal we should have to inject various predetermined toxins along with the hypertensor agents, indeed, I need not insist on the differences between experimental or spontaneous atheroma and arterio-sclerosis. Atheroma remains limited to the large trunks and medium-sized vessels, whereas arterio-sclerosis, a disease of intoxication, affects especially the viscera. This difference in the lesions explains how it is that atheromatous patients remain vascular subjects with a minimum of symptoms, whereas the subjects of arterio-sclerosis promptly become "visceral" subjects, and are exposed sooner or later to the gravest toxic accidents.

Of some 15,000 cases that I have collected, I have carefully investigated 1,980 with the following results: The most frequent ætiological factor was gout and its manifestations, gravel lithiasis (393 cases); then rheumatism (254 cases); syphilis (237 cases); alimentary habits (205 cases); and tobacco (188 cases). There were 57 cases following infective diseases, diabetes (51 cases); alcoholism (31 cases); malaria (23 cases); and the menopause (21 cases). Moral and nervous causes only accounted for 19 cases.

Whatever we may think of the value of statistics, these have an eloquence of their own. They show that tobacco, syphilis and alimentary habits cannot be discarded, as certain authorities would have us do, from the ætiology of arteriosclerosis. The present confusion on the subject of arterio-sclerosis is especially due to authors not having sufficiently defined the limits of the disease which they seek to describe on the strength of its anatomical characters rather than by its clinical characters. If we keep to the clinical aspect we shall recognise three principal forms of cardiacsclerosis—cardio-renal, which is the most frequent; cardio-sclerosis of myovalvular origin; and sclerosis of the cardio-bulbar type (Stokes-Adams' disease).

With regard to its clinical course, cardiosclerosis may be divided into four stages: a first stage characterised by heightened arterial tension of toxic origin (præ-sclerosis); a second, cardioarterial stage with cardiac degeneration; a third, mitro-arterial and a final stage, which may be wanting, characterised by disturbances due to cardiectasis.

The dominant symptom during the præsclerosis stage is hypertension, presumably of renal origin, this prepares the way for, and causes, the vascular lesions of arterio-sclerosis. At this stage the arterial lesions are reduced to a minimum. so that the disease is perfectly curable. This stage is characterised by hypertension, visceral meiopragia and intoxication, the last-named being consequent upon renal insufficiency, which is the constant and early symptom of arterial cardiopathies, even in the absence of albuminuria. The painful symptoms comprise angina pectoris, rheumatoid pains in the limbs, side stitch and intercostal pain, the arterio-spasmodic origin of which is shown by the success of the vaso-dilatation treatment inaugurated by Weber and Jaquet.

Towards the end of the first stage cardiosclerosis is accompanied by tachycardia and arhythmia. This tachy-arhythmia is soon accompanied by a bruit de galop, which is not easy to distinguish in consequence of the rapidity of the heart-beat. Then, too, there is alimentary toxidyspnœa, which must not be mistaken for uræmia. The latter does not disappear rapidly as does the dyspnœa of cardio-sclerous patients on a suitable

This brings me to speak of the asthma and emphysema which it used to be thought might determine asystole by dilatation of the right heart, but personally, I have never seen asystole follow asthma or emphysema. Asystole only supervenes in asthmatic, emphysematous subjects who have developed arterio-sclerosis. The heart only becomes dilatable in consequence of preexisting myocardiac lesions.

In the myovalvular form, in addition to the arterial lesions, we get lesions of the aortic or mitral valves. Clinically, this form manifests itself by the same toxic or meiopragic phenomena. The mitral lesion may lead to narrowing or insufficiency of the auriculo-ventricular orifice, a tolerably frequent consequence. In order to be enabled to distinguish the physical signs of mitral stenosis it is necessary to lower the aortic tension by rest, diet and hypotensive medication, and to slow the heart by giving digitalis. We then detect doubling of the second sound, attenuated and intermittent, presystolic roulement and diastolic snoring, as in all arterial cardiopathies. The functional disturbances are here of capital importance for mitral stenosis, itself productive of dyspnœa, is doubly so when complicated by arterio-sclerosis.

Mitral stenosis in the subjects of arteriosclerosis is accompanied by symptoms which are not met with in pure mitral stenosis, they being consequent on the extension of the arteriosclerosis to various organs and tissues. I need not insist on aortic stenosis and insufficiency, but it must not be forgotten that it is not the aortitis that does the harm in aortic insufficiency in the subjects of arterio-sclerosis, but the kidney which by the imperfect discharge of its functions favours the production of toxic disturbances. The disease is in the heart, but the danger is in the arteries, and especially in the kidney.

Arterio-sclerosis may be of aortic origin, as in syphilitic arterio-sclerosis, and it may remain for some time apparently a merely local disease which, however, in the course of months or years

is followed by the usual symptoms of arterial cardiopathy.

Many physicians attach great importance to the sinuosity and hardness of the temporal artery as a sign of the existence of arterio-sclerosis, but this state of the temporal artery is met with in pure hypertension without any vascular lesion, or it may be due to atheroma without concomitant arterio-sclerosis. Cerebral hæmorrhage again has been put forward as a consequence of arteriosclerosis, but it only occurs when the disease is complicated by interstitial nephritis.

Then, too, we must distinguish between the senile heart and the arterio-sclerous heart, for the proliferation of connective tissue that takes place in the cardio-vascular system of the aged, presents many points of difference with that of arterio-sclerosis.

With regard to the therapeutical indications, I need only remark that during the first stage, that of so-called præ-sclerosis, we must deal with the intoxication of renal origin and the hypertension, the former by milk or lacto-vegetarian diet, and the administration of diuretics: theobromine and thyminic acid: the latter by massage, muscular gymnastics, carbo-gaseous baths and vaso-dilators.

In the second stage milk diet is de rigueur, or we must, at any rate, reduce the introduction of alimentary toxins to a minimum.

In the mitro-arterial stage we must enjoin milk diet and the administration of theobromine and digitalis, diminishing the amount of liquids. At this juncture I should like to enter a protest against the abuse of certain drugs, which are only indicated at the end of the first stage and during the second stage, such as iodide of potassium, anti-sclerous serums, and certain mineral waters.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for rext week will be by Professor Julius Dollinger, M.D., Professor of Surgery at the University of Buda-Pesth. Subject: "The Extraction of the Roots of the Trigeminal Nerve, as an Operation substituting the Extirpation of the Gasserian Ganglion."

# ORIGINAL PAPERS.

# THE ESSENTIALS OF PHYSIOLOGICAL HISTORY.

By DAVID FRASER HARRIS, M.D., B.Sc.Lond., Lecturer on Physiology in the University of Birmingham.

ABSTRACT OF LECTURE II.

THE views of Aristotle on respiration and animal heat were first of all explained. Aristotle believed that air entered the heart to cool it; its innate heat tending to become "excessive." This idea that breathing was to cool the heart lingered in physiology until after Harvey's time. Galen knew of the diaphragm and intercostal muscles as respiratory, that division of the recurrent laryngeal abolished voice, and that division of the spinal cord compromised breathing. Vesalius in 1540 showed that artificial respiration would resuscitate a heart that had ceased beating.

Von Helmont (1577-1644) virtually discovered carbon dioxide as gas sylvestre about 1640. To Fabricius the object of breathing was generation of animal spirits, cooling the heart and getting rid of "fumes." Harvey's treatise on respiration was

Note.—These Lectures were delivered in the University of Birmingham during May, 1909. Abstract of Lecture I. appeared in our last week's issue. Lecture III. will appear in our next.

lost when his rooms in Whitehall were ransacked in 1642 by the soldiers of the Parliament.

The views of Thomas Willis (1621-75), a pupil of Harvey, were then described. The experiments by Boyle (1660) with the air-pump showed that in a partial vacuum a sparrow and a mouse died, and the flame of a candle went out. Hooke's experiment of 1667 before the Royal Society demonstrating life supported by artificial respiration was the next contribution. Borelli in Italy correctly solved several problems in the mechanics of respiration, while Richard Lower, of Oxford, shed light on its chemical aspect. John Mayow, of Oxford, virtually discovered oxygen in a physiological sense as "nitro-aerial particles." His conclusions were far ahead of their time, and his work misunderstood and forgotten. G. E. Stahl (1668-1723) put the hands of the clock of research back by explaining combustion and breathing in terms of "phlogiston."

The Rev. Stephen Hales (1677-1761) was one of the first men of science to understand ventilation. His ventilators were introduced into prisons, hospitals, the holds of ships and mines.

Joseph Black (1728-1799), at Edinburgh, enunciated the doctrine of "latent heat," and first showed the rôle of carbon dioxide in chemistry. Experiments of Hales with regard to an apparatus for purifying the air breathed over and over again in mines where the CO2 was absorbed by potash, suggested to Black the study of this gas. Priestley, Lavoisier, Cavendish and Crawford all acknowledge their indebtedness to Black. He first explained the formation of calcic carbonate in flime water. Black is generally recognised as the "Discoverer" of carbon dioxide—the discoverer of its fundamental chemical and physiological properties.

In 1772, Daniel Rutherford, a professor at Edinburgh, virtually discovered nitrogen as

'' mephitic gas.''

Joseph Priestley, on August 1st, 1774, by the use of a "burning glass" caused oxygen to separate from "mercurius calcinatus per se." He did not quite understand what he had discovered: it was oxygen or "oxygine," as Lavoisier called it; to Priestley it was "dephlogisticated air." Lavoisier, untramelled by the "phlogiston" theory, began where Priestley left off, and showed that animal heat and the heat of combustion were alike due to the oxidation of carbon and hydrogen in the animal and in the inflammable substance respectively. Scheele, the Swede, really knew of oxygen in 1773, but his experiments were not published until after Priestley's, and Priestley knew nothing of them. Lavoisier invented the first or ice calorimeter. Nitrogen he called "azote," the substance that would not support life. Adair Crawford's theory of the rôle of the blood in maintaining a constant temperature was described; it was based on errors in calculating the specific heats of arterial and venous blood; to him is due the water calorimeter (1788).

The important work of Pettenkofer and Voit, of Münich (1866), and the contributions by Bohr of Copenhagen; Haldane of Oxford; and Leonard Hill of London were alluded to.

The history of the extraction of the gases of the blood (Magnus, Davy, Liebig and Pflüger) was summarised. The history of growth of knowledge of tissue respiration was briefly gone into, as also that of the respiratory importance of

hæmoglobin (Funke, Hoppe, Vierorht and Stokes). A resumé of the history of animal thermometry brought the lecture to a close.

# AN EXPERIMENT TO DETERMINE THE VALUE OF COLOURED UNDER-CLOTHING FOR SOLDIERS. (a)

By Capt. J. M. PHALEN

AND
LIEUT. H. J. NICHOLS,
Of the Medical Corps of the United States Army.

WE wish to say frankly at the outset that our object in presenting this paper is to profit by discussion rather than to attempt to instruct and, accordingly, we shall simply give an explanation of what is being done by the U.S. Army in the Philippine Islands in regard to the effects of tropical light, in the hope that this account, even if it contributes nothing, may be of some interest here in India where the climatic conditions have given rise to so many observations on this subject. During America's short occupation of tropical countries, a number of men, but notably Major Woodruff, of the Army Medical Corps, have become impressed with the possibilities of the effect of tropical light on white men and have brought this question into prominence. During England's long rule in the Tropics, however, the question has been considered more thoroughly and the immediate cause of the work to be outlined is found in two articles by Sambon and Duncan in the Journal of Tropical Medicine, of February and March, 1907. Sambon, it will be recalled, photographed the spectrum of an electric arc after passing the rays through the skin of a native of India, and then constructed wearing material for white men which had the same effect. Duncan's article was promoted by Sambon's, and he gave practical instances from India to support Sambon's theories, with recommendations in regard to clothing. These articles came to the notice of the Inspector-General of the Philippines Division, and he urged that the matter be looked into. General Wood approved, with the remark that while the effects of the sun in these islands and in the hotter portions of India are very different, yet it is believed that it would be wise to have a careful investigation made as to the advantage to be derived from the use of underclothing of a colour to protect against this (the actinic) ray."

THE EXPERIMENT.

These recommendations were approved at Washington and on advice of the Surgeon-General 5,000 suits of the regular issue underwear and 5,000 hat linings were dyed orange-red, the colour selected being, in the words of the Surgeon-General, "as nearly as practicable that used by photographers to prevent chemical effects of the light used in their dark rooms and for the same reason." The matter was turned over to us for execution, with directions that half of a company wear the coloured underwear and the other half to act as controls, and that a special medical officer stay with the troops for a year to observe the results.

The question may suggest itself, why should this experiment be made? Why not adopt the clothing outright? For us there are two reasons. In the first place the whole subject is in a somewhat hypothetical state. Neither the effects of

(a) Abstract of Paper read before the Indian Medical Congress, Bombay, February, 1909.

light nor the remedies proposed are on any such firm ground as the need for sterilised water or mosquito nets and light clothing in the Tropics. Enthusiasts who have perhaps more fondness for ethnology and analogy than actual experience make it seem quite plain. Others, perhaps, equally biassed, hold that the ills of tropical life are all included in the results of infection, heat and moisture. Take, for instance, a sunstroke as an example of the unsettled state of opinion. Duncan's article is entitled "The Actinic Theory of Sunstroke," and he says there can be no doubt that this actinic theory of sunstroke is the correct one. Manson, however, says that in his opinion Sambon's pypothesis of the infectious nature of siriasis has more in its favour than any of the many theories that has been based on a purely thermic ætiology. On the other hand, Rogers has shown, quite conclusively, it seems to us, that sunstroke is co-related with a high temperature and a certain degree of moisture in the air.

EFFECT OF ACTINIC RAYS.

In the second place we have to deal with soldiers and with soldiers in the Philippine Islands, This fact narrows the field at once. If the ultraviolet rays are injurious, it would undoubtedly be of value to wear coloured glasses to protect the retina; this is not feasible, however, for soldiers who would discard them on the slightest provocation. Again soldiers' clothing, for military purposes, is already to a certain extent pigmented and certain articles of clothing, such as the hat are fixed beyond change. Again in the Philippines we have practically no sunstroke, although it is common enough in some seasons and places in the United States.

It seems desirable, therefore, that we should satisfy, ourselves of the value of these suggestions for our own conditions and environment before acting finally upon them. Granting, for the sake of trial, that the actinic rays are injurious to the white men's tissues, how can we measure and demonstrate these effects. Sunstroke must be excluded as it is so rare; heat exhaustion is by common consent admitted to be due to heat rather than light. There remains a group of complaints called sun traumatism by Manson, and we have a small number of cases which may be included in this group. The chief results, however, must be sought for under the rather vague headings of neurasthenia and anæmia.

Neurasthenia.—If loss of physical and mental tone is measurable in objective terms it has seemed to us that dynamometer and blood pressure readings should show it, and these are the special tests, one for the voluntary muscle nerve apparatus and the other for the involuntary, that we expect to rely most upon. These observations will be made at least every three months.

Anæmia.—Some work has already been done by medical officers on the blood, and among nearly 100 men observed for over a year by Capt. Wickline, there was an average loss of over 10 per cent. hæmoglobin; an increase of the number of red blood cells, and an increase of lymphocytes and decrease of polynuclears. Similar observations will be made on the men wearing coloured underclothing, and on controls.

### RESULTS OBTAINED.

Now 500 subjects with 500 controls have been selected from cavalry, infantry, and artillery in our widely-separated posts. After excluding men

with long tropical service and those who are for any other reason unfit, every other man in order of height has been ordered to wear the clothing and the other men to serve as controls. A special medical officer has been detailed at each post to keep the records and to observe the results. The records are kept on cards which require, beside, the special test mentioned, the following data: Age, height, nativity, colour of hair, colour of eyes, complexion, length of service, and length of tropical service; an account of previous medical history and medical history during the test; weight, pulse and respiration.

In addition to these 500 men, 75 men are to be studied more closely with the ergograph and blood pressure readings for effect of short exposures to the sun. A number of officers of the line and staff are also wearing the clothing and their opinion will be considered.

Some information has already been obtained by exposing photographic plates to sunlight after passing through the articles of our uniform. The most interesting result is that our campaign hat, which is apparently fixed for field work, is as opaque to chemical rays without a red hat lining as with it. As the lining increases the heat, it seems doubtful if the hat lining will be of any benefit for the campaign hat; for caps there is a slight difference for the orange-red lining over the ordinary lining coloured green, brown, or red. Our blue flannel shirt, however, is not as protective chemically as we had believed. We have other prints showing the absorptive power of each article of clothing. Other questions have come up such as the fastness of the dye, the increase of heat of coloured clothes, the relative value of a less gaudy garment, etc.

At present we are merely in a receptive mind, and while we believe that at the end of this test we can give some definite opinion on the merits of coloured underclothing for our soldiers, at present we are in the strictly agnostic mood.

# SUPRA-PUBIC PROSTATECTOMY. (a)

By G. P. NEWBOLT, F.R.C.S.Eng.,

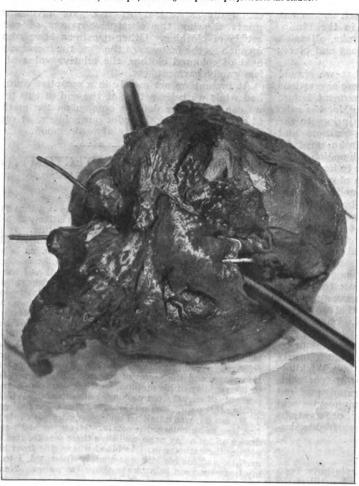

Surgeon, Royal Southern Hospital, Liverpool,

(Concluded from page 526.)
The chief danger in the operation is the fact that the patient's kidneys are diseased, and this is likely to tell more in this class of case than in any other. It is also rather difficult to ascertain beforehand what the condition of the patient's kidneys is when, as is so often the case, cystitis is present. Again, he is often the subject of chronic chest mischief; and, as I have said, it is as well to have your patient under observation for a time in order to wash out the bladder, determine the state of the kidneys, and, if possible, improve the general condition. In a doubtful case it is a question whether preliminary supra-pubic drainage is not the safer plan. I see Freyer has done it three times in his last 119 cases. In the first place, the cystitis can be treated, and, secondly, acute retention is at once relieved. Again, time is saved at the second or enucleation stage, and the secret of Freyer's success must lie in the rapidity of his method, which lessens shock and prevents ill-effects from prolonged anæsthesia. writing this paper, and on October 15th last, a patient, T. B., at. 63, was admitted under my care with retention due to an enlarged prostate. His urine had been drawn off for a day or so, and then there was trouble in getting the catheter in. As blood was oozing from his urethra, and his bladder was acutely distended, I told my house-surgeon to aspirate above the pubes. Next

<sup>(</sup>a) "Liverpool Medico-Chirurgical Journal," January, 1909.

day he filled up again, so I opened his bladder above the pubes, washed out some rather foul urine, and drained him with a view to subsequent prostatectomy. At the operation his bladder was enormously distended, and the finger felt the sacrum plainly. The prostate itself was pushed forwards under the pubes,

(6) A variety in shape; the elongated portion projects into the bladder.

(2) The same specimen with probes passed down the ejaculatory ducts.

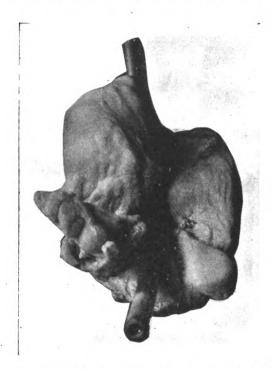

so that only the urethral opening could be felt from the interior of the bladder, though the gland itself could be plainly felt from the rectum; after drainage the prostate returned to its normal position, and could be felt as a distinct projection into the bladder. This man's condition slowly improved, his pulse fell, and his tongue became moist. Any operation for removal of the prostate at the time of his admission would, I am convinced, have proved fatal. His urine contained 1.5 per cent. of urea. On November 3rd, eighteen days after the supra-pubic drainage, I removed his prostate. The actual enu-cleation took about four minutes, and he was under the anæsthetic (which he took badly) for twenty minutes. There was more hæmorrhage than usual, and I washed hisbladder out with very hot water passed through a catheter in his urethra until the washings were clear. The prostate weighed two ounces, and the supra-pubic wound needed enlarging before the tumour could be delivered. His pulse ran up from 80 to 124 the same evening, but since that date he has had no further trouble, and is conva-

lescing favourably.
What are the after-results if the operation is a success? Does it prove a complete cure? The answer is Yes in the great majority There are, however, of cases. instances in which this is not so. There may be frequency of micturition after operation, stricture or a sinus giving trouble for a varying period; stone may form as a phosphatic deposit about the site of enucleation; there also may be loss of sexual power. With regard to stricture, I fancy that some degree of contraction at the point at which the urethra is torn is the cause of this trouble, and in all probability it may be avoided by the passage of instruments after

operation.

A typical instance is that of a man, at. 52—fairly young for this operation—whose prostate was removed abroad in March last. As a result he was unable to hold water at night, and the most he could retain in the daytime was three ounces. This, of course, prevented his keeping any social engagement. Under an anæsthetic, I forced a Lister's bougie through an obstruction about the triangular ligament, guiding it with my finger in the rectum, and then dilated him up to the full size, i.e.,  $\frac{15}{18}$  Lister. Ten days later I passed a large Lister's bougie with eucaine. As a result of this treatment he was able to retain nine ounces of urine, the dribbling disappeared, he was quite comfortable, and, I think, will have no further trouble. Another case was one of my own, where I did

not pass an instrument at all after operation; as a result, he got complete retention, and I had to torce a Lister's bougie through. After passing this three or four times, there was no after-trouble, and the man is quite well at the present time, four years after operation. The peculiar thing about this case was that the suprapubic wound and the stricture both closed tightly at the same time, and though I tried to get a probe the same time, and though I tried to get a probe through and open up the supra-pubic wound, I failed to do so. On the other hand, when there is trouble in getting the supra-pubic wound to close, the passage of a catheter very soon puts this right. I think that the cause of this stricture lies in the removal of membranous urethra; Freyer says he does not get this complication, and it may be that he is careful not to remove more urethra than he can help. In future I intend paying more attention to this point. I think the persistent sinus is rare: the first case I did had a little trouble, but it cleared up after passing a catheter once or twice. Only the other day I removed three stones from the bladder of a man with an enlarged prostate; yet in spite of this the supra-pubic wound closed quite easily. If the

(3) Parts removed from a gentleman, æt. 63, in whom they shelled out easily, leaving portions of the urethra behind. The patient is quite well after three and a half years.

phosphates form at the edges of the supra-pubic opening, the administration of boracic acid internally

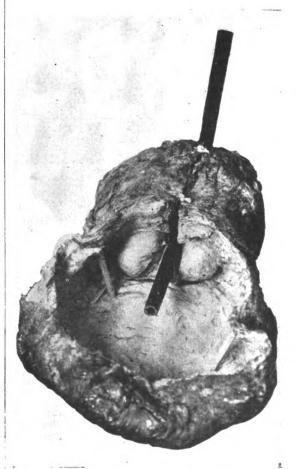

soon clears this away.

The question of the loss of sexual power must be considered. I am told that Freyer's youngest patient is only 46; and if one is going to operate upon men at this age, they naturally will want to know something about this point. I am also informed the man in question is quite sound. If you examine the specimens, in some the ejaculatory ducts are to be seen torn across; in others they are not. This depends upon the sort of case you have to deal with: if it is a total enucleation in one mass, as in most of the specimens shown, the ducts are torn; if the adenomata shell out, leaving the greater part of the urethra, the ducts may be uninjured.

Frequency of micturition sometimes remains for a while, together with a little dribbling of urine. The passage of a catheter once or twice will usually improve matters, and it is necessary when operating to keep close to the prostate and so avoid injury to the neck of the bladder.

(7) The reflected portions are pieces of envelope or surgical capsule separated after removal. Microscopically they consist of prostatic

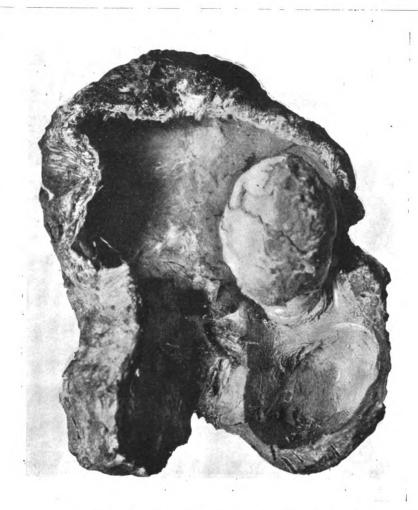

(8) Bladder from patient with enlarged prostate, showing the sub-mucous projections of the prostate into the bladder.

Epididymitis is a frequent complication, but does

not give rise to much trouble.

Mortality.—We have already touched upon this point, which must always be a consideration in the class of patients dealt with, i.e., unsound men. Freyer says that few of his patients were free from one or more complications, such as cystitis, stone in the bladder, pyelitis, kidney disease, diabetes, heart disease, thoracic aneurysm, chronic bronchitis, paralysis, hernia, hæmorrhoids, etc., so that his success is very wonderful. Whilst, however, considering the risk of operation,

pain. I taught his son how to wash out his bladder, and this gave him a little relief. Gallic acid internally usually checked the hæmorrhage for a time, but his condition during the last three or four years of his life was most pitiable. He had nine years' catheter life, and died at the age of 74. I have little doubt that operation at the onset of catheter life would have saved him infinite pain, and at the same time would have prolonged his life. Again, a man may go on with a certain amount of discomfort until he is very old, and then he gets retention. However careful one is,

(9) Same specimen showing the prostate enucleated from the left side and turned forward, leaving the sheath behind.

we must not forget the other side of the picture. The discomfort—or, I should rather say, absolute misery—that a man goes through who has complete retention can only be realised by watching a case of this sort. Take the following instance. An old gentleman, with an enormous prostate and, as the result of straining, a large hernia, with a bunch of hæmorrhoids complicating matters, also had a big rectal polypus. He was nervous and would hear of no operation. I managed, with the help of cocaine, to secure the rectal polypus, but I never managed to get possession of his prostate. I saw this man on and off for several years, and he died in the greatest misery. His bladder got into the most irritable condition, so that he passed his catheter every half-hour in attempts to relieve himself; he bled at intervals, and was never free from

the use of che catheter speedily upsets the balance, and he quietly goes downhill; his tongue becomes dry, he wanders in his mind, and dies in an uræmic condition. Here there has been no special indication for operation early on, and it is useless at the later stage, and he does not suffer much.

I can hardly leave the subject without making a few remarks about the pathological anatomy of the gland in question. There is an excellent paper by Cuthbert Wallace on the subject in the British Medical Journal, January 30th, 1904, to which I may refer you. There is no doubt that the parts removed differ according to circumstances. In the majority of cases the whole enlargement, including the prostatic urethra, is removed, together with a variable quantity of envelope or capsule derived from the expanded portion

of the prostate, which has been stretched and flattened out by the growth of the adenomata from within. The amount of envelope left behind depends upon the depth at which the enucleating finger effects its entrance. In some cases adenomatous masses only are shelled out laterally and from behind, and portions of the urethra remain behind (Specimen No. 3). In no instance should the recto-vesical fascia be opened up or the venous plexuses be injured; and a portion of envelope of prostatic tissue is usually, if not invariably, left behind, which accounts for the little bleeding and the absence of extravasation in the great

majority of cases.

The envelope or "surgical capsule" is a pathological formation, and it follows, I take it, that it is impossible to remove a normal prostate, for this envelope is not present, so that the recto-vesical fascia would be injured and fatal hæmorrhage or extravasation would occur. That prostatic tissue is left behind has been proved by examination of the "shell" left arter enucleation of the prostate in the post-mortem room.

I have specimens showing this.

# **OUT-PATIENT'S ROOM.**

ST. THOMAS'S HOSPITAL.

Fracture of the Atlas.

By Mr. EDRED CORNER, M.C., F.R.C.S.

A CABMAN, æt. 50, was dozing in a chair on a Sunday afternoon, and, in nodding, he rolled out of his chair into the corner of the room. His head was flexed at the time, and there was no great violence used. The pain at the time was described as "simply shocking." It was situated high up in his neck. He was assisted to rise, though there was no paralysis or anæsthesia, etc. Having been put to bed, he remained there rather out of expediency than actual necessity. It was not till the fifteenth day that he came to the out-patients' department at St. Thomas's. When seen there he was found to have pain and rigidity in the upper part of his neck. He also complained of pain along his right great occipital nerve. A skiagraph was taken which revealed fractures of the pedicles of his axis. He was treated with quiet and rest, followed by massage. He commenced to drive his cab about again in twelve weeks' time. Nearly seven months after the accident the movements of his head were quite good, but he still complained of curious numb feelings over the area of his left great occipital nerve.

In giving a description of the injury, Mr. Corner said: The anterior skiagraph of the spine showed nothing. The lateral view shows very distinctly a fracture of each pedicle. That on the right side is displaced a little upwards, so that the ends of the fragments are seen above those of the left pedicle. The fact that the fragments of the broken left pedicle are but little displaced is seen in the obscurity which it leads to in the lower part of the fracture. The greater displacement of the fragments of the right side explains the greater involvement of the corresponding great occipital nerve. The line of the fracture is as follows: Above it starts at the outer and posterior part of the superior articular processes of the axis and passes downwards and backwards, to end on the inferior surface of the pedicle just in front of the inferior articular process. The arch of the axis is in consequence completely separated from the body. It is, however, held in its normal position by the ligaments. The body of the axis can be seen to be displaced a little forwards. This forward movement of the body is checked, as in Lowson's case, by the locking of the odontoid process with the anterior arch

Case of Unilateral Rotatory Dislocation of the Atlas,

of the atlas and the transverse ligament.

with Fracture of the Anterior Arch.

J. L., æt. 21, fell off a horse on to his forehead. Beyond making him see stars, he was none the worse and got up and rode his horse home. He came up to St. Thomas's Hospital for advice on account of a stiff and painful neck. As rubbing and liniments after a fortnight had done no good, he was admitted.

On examination, it was seen that the patient carried his head a little flexed and turned to the right. movements were very limited and painful. Rotation of the head to the left side was practically abolished. The left transverse process of the atlas is easily palpable between the mastoid and the angle of the jaw. On the right side it cannot be felt, the finger sinking into a groove. Further palpation gives the impression that the process is displaced backwards. There is obviously a dislocation of the right side of the atlas. Just below and on the right side of the back of the neck there is a prominence of the middle cervical vertebræ, which is due to some accompanying rotation of the vertebræ below the injury. After a few minutes' standing the man becomes fatigued.

An examination made on a later day confirmed the above in all particulars, and it was further remarked that he could rotate his head to the right or injured side and not to the left or uninjured side. At first he was unable to open his mouth fully, so that it was impossible to make a full examination of his pharynx. His articulation was also thick and indistinct. was able to swallow what food he could get into his mouth. These disabilities slowly improved, so that when an examination of his pharynx was possible, the left transverse process of his atlas could be felt displaced forwards.

The skiagraph shows the unilateral dislocation of the atlas and the callus which has resulted from the fracture of the anterior arch of the same bone. As in all other skiagraphs it is practically impossible to be certain of the condition of the odontoid process. It was thought at the meeting of the Clinical Society at which this case was shown that it was not broken.

# SPECIAL REPORTS.

# GENERAL MEDICAL COUNCIL.

EIGHTY-NINTH SESSION

FIRST DAY.—Tuesday, May 25TH, 1909.

The President, SIR DONALD MACALISTER, in the Chair.

THE notification of the appointment of two members of the General Medical Council was read: (a) Frederick Taylor, M.D., F.R.C.P., M.R.C.S., as representative of the University of London for one year from February 24th, 1909; (b) David Neilson Knox, M.B., C.M., as representative of the Faculty of Physicians and Surgeons of Glasgow from May 3rd, 1909, to April 6th, 1911.

Dr. Taylor was introduced by Dr. Norman Moore, and Dr. Knox by Dr. Norman Walker.

The PRESIDENT then delivered his address. After referring to the early and mournful death of Dr. Lindsay Steven since the last session, and saying a few well-chosen words about his great worth as a physician, a teacher, and a philanthropist, he men-tioned that regrettable failures of health had led to the retirement of Dr. Pye-Smith and Professor Young, and spoke feelingly of the great help these gentlemen had afforded the Council on various occasions. He also reminded the Council of the great loss the profession had sustained in the death of Mr. Wheelhouse. He said, in continuation :-

The University of London has sent us a distinguished member of its Senate in the place of Dr. Pye-Smith, and the Faculty of Glasgow its Visitor in the place of Dr. Lindsay Steven. To Dr. Frederick Taylor and Dr. David Knox we offer the welcome which is due to their personal merits and services, no less than to their professional eminence. We may count with con-fidence on receiving from both the benefit of their

special knowledge and experience.

In accordance with my duty as President, it has fallen to me to make representations to the Government, through the Lord President of the Privy Council, on various matters regarding which resolutions were passed in November. The Council requested that steps should be taken for the appointment of a Royal Commission to inquire into the evil effects produced by the unrestricted practice of medicine and surgery by unqualified persons. The Lord President has decided to make preliminary inquiries on the subject, through the Local Government Board. A circular has accordingly been issued to Medical Officers of Health, asking for information concerning the extent of the practice complained of, and its effects on the general health, within their several districts. When the replies are received, the Lord President will be in a position to determine what further steps are desirable in the interests of the public.

From the Colonial Office the Executive Committee has received a copy of an Act of the General Assembly of New Zealand, entitled the Quackery Prevention Act, 1908. This Act is directed against obnoxious forms of irregular practice, and imposes heavy penalties for these offences. The Executive Committee have replied that they would welcome similar legislation applicable to other parts of the British Empire.

In the Tuberculosis (Ireland) Bill, as originally presented to Parliament, the duty of advising the Irish Local Government Board with reference to the application of the proposed law was assigned to the Irish Branch Council; but no provision was made for meeting the expenses the Branch Council must thereby incur. On discussing the question with the authorities, it appeared that no grant from public funds was likely to be made for the purpose. The situation was dealt with by transferring the duty in question to the Presidents of the Royal Colleges of Physicians and Surgeons in Ireland, and with this change the Bill has passed into law.

By the Bill for the Registration of Nurses, concerning which a communication was received from the Privy Council on November 13th, it was proposed to establish a General Nursing Council for the United Kingdom, of which one member out of sixteen was to be appointed by the General Medical Council. The Nursing Council was to frame rules inter alia "regulating, supervising, and restricting within due limits the practice of registered nurses." It was represented by you to be expedient that the Medical Council should stand in the same relation to the body concerned with nurses as it does to the Central Midwives Board. At the Privy Council Office note was taken of your views, and I have ground for believing that, should the Bill be proceeded with during the present session, it will be proposed to amend it in the sense you indicated, the Executive Committee being entrusted with the function which under the English Midwives Act is committed to the English Branch Council. Should this arrangement be sanctioned by law, the expense falling on the Council would be trifling, as the matters passing under the review of the Executive Committee could be dealt with at its ordinary meetings. unable to obtain any assurance that a subsidy from public moneys would be granted to the Council in respect of this public service. As, however, other proposals dealing with the registration of nurses are under consideration, and as opinion appears still to be divided on the general question, it is probable that legislation on the subject will be deferred.

By your direction I communicated the Council's resolution of November 28th respecting the General Anæsthetics Bill, 1908, to the Government Departments concerned. The resolution supported the proposal to restrict to qualified medical practitioners the administration of drugs with the object of producing unconsciousness during medical, surgical, or obstetrical operations. In the present session of Parliament another Bill having a similar purpose has been introduced. Both Bills propose that dentists registered after a certain date shall not be entitled to administer general anæsthetics unless they possess a medical qualification. On this particular proposal the Council did not pronounce an explicit opinion, though its resolution on the general principle involved might be held to indicate its views with sufficient clearness. Now, however, we are asked in various quarters to express an opinion on the point, and in particular to give an answer to a question bearing upon it, which is submitted on behalf of the Lord

President. The Council will therefore be called on to consider whether, apart from the saving to existing dentists of their customary practice, it is expedient in the public interest to confer in future on dentists who have no medical qualification, express legal authority to administer general anæsthetics to persons requiring dental operations. When it is kept in mind, first, that unless skilled attention is given to the state of the patient's bodily health no general anæsthetic is invariably "safe," and, secondly, that in dental practice the anæsthetist is often the operator also, it will be seen that the proposal contained in the Bills referred to is not without some justification in the interest of the public profection.

The Registrar has received replies from the licensing bodies to his inquiry as to the degree in which effect has been given to the Council's recommendation—that candidates for medical qualifications should be required to produce evidence of having received practical instruction in the administration of anæsthetics. Nearly all the licensing bodies have answered that this requirement is already or will in future be enforced. The Council is thus justified in its contention, that fresh legislation to this end, which to be effective must be penal in character, is neither expedient nor necessary at the present time.

With the assistance of the legal advisers, I have

With the assistance of the legal advisers, I have drawn up a memorandum on the penal procedure of the Council, showing the nature of the actions which have been held by it to constitute infamous conduct in a professional respect. This memorandum has been forwarded at his Lordship's own request, to the Secretary of State for the Colonies, and communicated by him to the Boards of Inquiry constituted by the medical enactments of the several Crown Colonies. It is to be hoped that the information conveyed will be useful in promoting uniformity of judicial action in professional matters within the Colonies concerned.

The penal cases to be considered during this session are not numerous, though some of them are grave. They include one in which it will be necessary to inquire into a charge of "covering" an unqualified assistant. That such charges have now become rare testifies to the efficiency of the action taken by the Council some years ago, and to the praiseworthy ambition of the profession to dissociate itself entirely from a practice which experience had shown to be liable to grave abuse. A few charges against dentists have come before the Dental Committee, who will report to the Council on the facts of each case. energies of the British Dental Association are actively engaged both in challenging what it deems to be reprehensible conduct on the part of registered practitioners of dentistry, and in applying with marked success a recent interpretation of the Dentists' Act to the suppression of unwarranted pretensions to professional skill put forward by unqualified persons. A judgment delivered in the Court of Appeal last week appears to limit the application of that interpretation. have asked our legal advisers to state for the information of the Council the precise nature of the

I am informed that, at the instance of the Association, an injunction for the restraint of dental practice by a company of unqualified persons has been granted by the High Court in England. This decision confirms the similar judgments of the High Courts in Ireland. But it is further held to impose on companies of unregistered practitioners the same disabilities as are now imposed on individual persons. Should this opinion be well-founded, the Act will prove even more effective than it has hitherto appeared to be for the prevention of irregular practice under cover of the Companies' Acts.

The active exercise of its judicial functions is obligatory on the Council, and the effects are, without doubt, salutary from the professional as well as from the public point of view. But these functions involve a heavy drain upon the Council's funds, and it is not easy to see how, under the present law, the drain can be obviated or moderated. Two recent cases, which were unusually prolonged, cost us in legal and other necessary expenses nearly £2,000. The result is that

the financial year closed with an aggregate deficit of over £650 in the accounts of three Branch Councils. Though the cases under the Dentists' Act were also both numerous and important, the simpler methods of investigation which the Act permits made the proceedings much less costly, with the result that the Dental Fund closed with a sufficient surplus to meet unforeseen emergencies.

It is fortunate that for each of the three preceding years the receipts of the Branch Councils exceeded their expenditure. Except, perhaps, in the case of the Itish Branch, the accumulated surpluses will enable them to meet the exceptional deficits of the present

Dr. Langley Browne has given notice of a motion that the proper steps be taken for adding to the Council a thirty-fifth member, to be elected by the practitioners of England and Wales. It will be for the Council, and afterwards for the Privy Council and for Parliament, to consider whether it is in fact expedient that the addition should now be made. In the near future we shall have an additional member from Ireland, as provided by the recent Universities Act; and we may also expect two additional members from the Universities of Wales and of Bristol. In coming to a decision on this question, it will be desirable to have regard, on the one hand, to the inelasticity of our finances, and of our Council Chamber, and on the other hand to the unity and efficiency of the Council as at present constituted. By the terms of the Medical Act, the question to be decided resolves itself simply into a question of "expediency." In other words, it is a question to be answered in the light of such practical considerations as I have ventured to recall to your attention, without seeking to prejudice your decision.

The Education Committee have had a further opportunity of reviewing the admirable digest of facts relating to the medical curriculum which was included in their report of last November. They will probably be prepared to offer to the Council certain definite conclusions, on which action may be taken if action is

required.

The Board of the Apothecaries' Hall of Dublin have informed the Registrar that they have determined to postpone until July 1st the resumption of their "Preliminary Examination in Education," concerning which the Council, on the recommendation of the Education Committee, expressed a strongly adverse opinion at its last meeting. The Executive Committee will report on the reply to this intimation which they deemed it their duty to forward to the Board. At a time when two newly-constituted teaching Universities, each with its own preliminary examinations, are in process of organisation in Ireland, it is difficult to perceive that any advantage to medical culture can arise from the proposed incursion of the Apothecaries' Hall into the sphere of general secondary education and examination.

The period for which the Council, on the applica-tion of the Apothecaries' Hall, appointed Sir Lambert Ormsby to act as an assistant examiner under the provisions of the Medical Act, 1886, will shortly expire. An application for a fresh appointment will be submitted to you on behalf of the Board. The Council will, I feel sure, recognise that Sir Lambert has discharged with efficiency the duties imposed upon him

by the Act.

The Executive Committee, in pursuance of the Council's instructions, have, with the assistance of our legal advisers, drafted a standing order applicable to cases of medical and dental practitioners who voluntarily apply for the removal of their names from the Medical or the Dentists' Register. Should this standing order be approved, it will provide for a casus omissus in the procedure of the Council, and remove a difficulty that has occasionally arisen.

On Saturday last we received from the Lord Pre-sident a copy of the draft charter prayed for by the British Medical Association, with a request for any observations the Council may have to make thereon. The draft charter proposes that certain powers, which are of a comprehensive character, shall be conferred on the Association. Some of the powers appear at first sight to trench on the statutory functions of the

Council, and these will require your careful consideration. It will probably be convenient that, in the first instance, the Executive Committee, in consultation with the legal advisers, should examine the draft charter, and report to you on the provisions that specially concern the Council.

Moved by Dr. LITTLE, seconded by Dr. NORMAN MOORE, and carried by acclamation: "That the President be thanked for his address, and requested to

let it be printed in the minutes."

Moved by Dr. NORMAN MOORE, seconded by Sir JOHN MOORE, and agreed to: "That the following constitute the Business Committee — Dr. Norman Moore, Chairman; Mr. Morris, the President, and Sir Christopher Nixon."

Moved by Dr. NORMAN MOORE, seconded by Mr. Thomson, and agreed to: "That the Council adjourn after 4 p.m. to enable certain committees to meet for

the completion of their reports."

Moved by Dr. McVail, seconded by Dr. Saundby, and agreed to: "That the following yearly tables be received and entered in the minutes

(a) I. and II. Tables showing results of Professional Medical Examinations during 1908.

(b) Table showing results of Professional Examinations for Qualifications in Sanitary Science, Public Health, or State Medicine during 1908.

(c) Table showing results of Professional Dental

Examinations during 1908.

(d) Table showing results of Preliminary Examinations during 1908.

(e) Answers sent by the medical authorities as to the exemptions granted by them in any part of their examinations during the year 1908.

(f) Table showing results of competition held in January, 1909, for Commissions in the Indian Medical Service.

Moved by Dr. McVail, seconded by Dr. Caton, and agreed to: That the thanks of the Council be conveyed to the Under-Secretary of State for India for the returns which he has again furnished to the Council, with the request that these returns may in the future continue to be furnished to the General Medical Council."

Moved by Dr. LANGLEY BROWNE, and seconded by Dr. McManus: "That representations be made to the Privy Council that it is expedient to confer on the registered practitioners, resident in England and Wales, the power of returning an additional member to the General Council."

After a short discussion, the motion was put, and the PRESIDENT announced that it had been carried by a majority of the members present: 17 for, 5 against,

8 did not vote, 3 absent.

Moved by Mr. Tomes, seconded by Mr. Morris, and carried: "That it be a further representation to the Privy Council that the addition in question be not made until the next ensuing general election of direct representatives."

Moved by Dr. Adve-Curran, and seconded by Dr. McManus: "That reports by Assistant Examiners in Surgery, of the Apothecaries' Hall of Ireland, be dis-

continued for the present."

After a discussion, the motion was lost: 5 for, 14

against, rr did not vote, 3 absent.

Moved by Dr. Adye-Curran, seconded by Dr.

McManus, and carried: "That Sir Thomas Myles, M.D., F.R.C.S.I., be appointed an Assistant Examiner in Surgery to the Apothecaries' Hall, Dublin, for a period of four years, in lieu of Sir Lambert Ormsby, who retires by rotation, his term having expired."

Moved by Dr. NORMAN MOORE, seconded by Mr. Thomson, and carried: "That the report by the Executive Committee on the proposed Preliminary Examination by the Apothecaries' Hall, Dublin, be received and entered in the minutes."

The report had reference to a letter received from the Secretary of the Apothecaries' Hall, Ireland, dealing with the postponement of the resumption of the Preliminary Examination in Arts till July 1st. 1909, after which date it will be revived. Dr. ADYE-CURRAN said this was a question of expediency, and not in opposition to the General Medical Council.

Moved by Dr. NORMAN MOORE, seconded by Mr.

MORRIS, and agreed to: "That the following report by the Executive Committee on the subject of voluntary withdrawal of names from the Medical Register and Dentists' Register, be received and entered in the minutes ":-

REPORT.

The Executive Committee having, on November 27th, 1908, presented to the General Council a report as to the course that should be followed in the case of voluntary applications from practitioners for the re-moval of their names from the Medical Register together with a proposed standing order, the General Council resolved that Mr. Lushington's opinion on the subject should be circulated amongst members, and that the further consideration of the report should be adjourned till the legal advisers had prepared a corresponding standing order with regard to dentists.

Mr. Lushington, as will be seen from the standing order, has now drafted regulations which will apply to both medical and dental practitioners.

"Standing Order, Chapter XIII., Rule 11.—Proposed new paragraph to precede the rest of the Rule:—

"Every application by a registered medical practitioner or dentist for the removal of his name at his own request from the Medical or Dentists! Persister own request from the Medical or Dentists' Register shall be accompanied by a statutory declaration, to be made by the applicant, that he is not aware of any proceedings or of any reason for the institution of any proceedings which might result in establishing cause for the erasure of his name from the Medical or Dentists' Register without his consent, or for depriving him without his consent of any qualification or licence entitling him to be registered.'

On motion from the CHAIR, it was resolved: "That the Council adopt the standing order which has been prepared by the Council's Legal Assessor, and recom-

mended by the Executive Committee."

Strangers then, by direction from the Chair, withdrew, in order that the Council might consider in camera an item in the programme of business.

The Council subsequently adjourned.

SECOND DAY.-WEDNESDAY, MAY 26TH, 1909.

The President, SIR DONALD MACALISTER, in the Chair.

The minutes of the last meeting were taken as read and confirmed.

The Council considered the case of Robert Kirk, The Council considered the case of Robert Kirk, formerly registered as of Delmynden, Carshalton, Surrey, but now of Willington, co. Durham, M.B., M.S., 1897, Univ. Glasgow, who had been summoned to appear before the Council on the following charge as formulated by the Council's solicitor: "That you abused your position as a medical man by committing adultary on various occasions with Lawre Sorth adultery on various occasions with Laura Sarah Hepple, the wife of Oliver Hepple, when you were professionally attending her and her children, Nellie, Ivy, and Olive Isabel. And that in relation thereto you have been guilty of infamous conduct in a professional respect.'

The complainant was Mr. Oliver Hepple.

Mr. Kirk was called, but did not answer to his notice, nor was he represented by counsel or solicitor. Mr. Oliver Hepple, the complainant, attended, accom-

panied by Mr. Hempson, his solicitor.
The Council's solicitor read the notice and a letter from Mr. Kirk, which had been received since the preparation of the documents and evidence. Mr. Hempson then addressed the Council on behalf of the complainant, and produced documentary evidence to show that Mr. Kirk had been in medical attendance on Mr. Hepple's family to a very recent date, which

He called Mr. Hepple as a witness, and examined him as to the accuracy of his declaration. Mr. Hepple

answered a question put to him by the Legal Assessor.

Strangers having been re-admitted after the Council had deliberated in camerá, the President announced the decision of the Council as follows:—

Mr. Hempson, I have to announce to you that the Council have judged Robert Kirk to have been guilty of infamous conduct in a professional respect, and have directed the Registrar to erase from the Medical Register the name of Robert Kirk.

The Council next considered the case, adjourned from May 27th, 1908, of Christopher Richard Kempster, registered as of Whitehall, Bank Place, Collins Street, Melbourne, Mem. R. Coll. Surg. Eng., 1896, Lic. R. Coll. Phys. London, 1896, who had been summoned to appear before the Ccuncil on the following charge, as formulated by the Council's solicitor:

"That you have accepted and continue to hold the appointment of Chief Surgeon to the Freeman and Wallace Electro-Medical Institute, of Melbourne and Sydney, Australia, a company which habitually seeks." to attract patients by the insertion in the Argus newspaper of advertisements of a scandalous, offensive and indecent nature, accompanied by a portrait of yourself and a statement of your qualifications, and that in relation thereto you have been guilty of infamous conduct in a professional respect."

The complainants were the London and Counties-

Medical Protection Society, Limited.

Mr. Kempster was called, but did not answer to his-

The London and Counties Medical Protection Society, Limited, were represented by their Secretary, Dr. Hugh Woods.

The Council's solicitor having read the notice, Dr.

Hugh Woods opened the case on behalf of the complainants, and put in copies of the advertisements of which the Society complained.

which the society complained.

In the absence of the accused practitioner, the Council's solicitor read the letters of explanation which had been sent by Mr. Kempster.

After the Council had deliberated in camera, and

strangers having been re-admitted, the President announced the decision of the Council as follows:—

announced the decision of the Council as follows:—
Dr. Woods, I have to announce that the Council have adopted the following resolution:—
"That the Council do now judge Christopher Richard Kempster to have been guilty of infamous conduct in a professional respect, and do direct the Registrar to erase from the Medical Register the name of Christopher Richard Kempster."

The Council considered the sease of Christopher William

The Council considered the case of Charles William Brown, registered as of 7 Chorlton Road, Hulme, Manchester, M.B., Mast. Surg., 1889, Univ. Edin., who had been summoned to appear before the Council on the following charge, as formulated by the Council's solicitor:—"That you have employed as your assistant in connection with your professional practice a person not duly qualified or registered under the Medical Acts, namely, Mr. — Amery, and have knowingly allowed him on your behalf to attend and treat patients in respect of matters requiring pro-fessional discretion or skill, and that in relation thereto you have been guilty of infamous conduct in a professional respect."

The complainant was Mr. Thomas George Paterson. Mr. Brown attended in answer to his notice, accompanied by Mr. A. H. Bodkin, counsel, instructed by Mr. W. H. Martin, King Street, Cheapside, E.C. Mr. Paterson attended, accompanied by Mr. Alfred

Tarbolton, of Messrs. Brett, Hamerton and Tarbolton,

solicitors, of Manchester.

The Council's solicitor having read the notice, Mr. Podkin took a preliminary objection to such of the declarations as had not complied with the Ccuncil's Standing Orders as to time, and to which he had consequently not had adequate time to prepare

The President informed him that he would have an opportunity to object to any of these declarations as they were reached.

Mr. Tarbolton proceeded to address the Council in support of the complaint. The statutory declarations by Mrs. Marianne Simpson and Miss Jane Stewart Simpson, and the supplementary declaration by Mrs.

Simpson, were read and put in.

Simpson, were read and put in.

Mr. Tarbolton referred to the declarations by Mrs.

Emily Gertrude Pinder, Mrs. Elizabeth Lea Greenwood, and Miss Jessie Gower Taylor, and was proceding to refer to that of Mr. Edward Arthur
Burgess, M.R.C.S., L.S.A., when Mr. Bodkin took
objection on the ground that the declaration was dated
as recently as May 18th, 1909, and that, though he
had given notice to the complainant's solicitor to produce all essential witnesses, Mr. Burgess was not

present. The Legal Assessor advised that the declaration should be admitted, as the Council had no power to compel the attendance of witnesses, but that, in the absence of a witness counsel were allowed considerable freedom in dealing with his declaration.

Mr. Tarbolton called Mr. Thomas George Paterson

and Mrs. Marianne Simpson, and examined them as witnesses. They were cross-examined by Mr. Bodkin, and the latter answered questions put to her by the Legal Assessor and by a member of the Council, through the chair.

Mr. Tarbolton next called Miss Jane Stewart Simpson, and examined her as a witness. Mr. Bodkin did not cross-examine.

Mr. Tarbolton read the declaration by Miss Jessie Gower Taylor, Miss Elizabeth Lea Greenwood, Mrs. Emily Gertrude Pinder, and a supplemental declaration by the same witness, and Mrs. Sarah J. Holmes, Miss Agnes Kate Simpson, and Mr. Edward Arthur Burgess, M.R.C.S., L.S.A., all of which he put in.

This completed his evidence.

Mr. Bodkin called Dr. Thomas Arthur Helme and Dr. Arthur Wilson Chapman, J.P., as witnesses, and examined them as to Mr. Brown's professional and personal standing in Manchester.

The Council then adjourned.

# THIRD DAY .- THURSDAY, MAY 27TH, 1000.

The President, Sir DONALD MACALISTER, in the Chair.

The minutes of the last meeting were taken as read and confirmed.

The President announced that he had received from the Privy Council a copy of Bristol University Bill, which had passed its second reading in the House

of Lords, and that the following were the clauses

which affected the Council :-

7. The University is hereby empowered to hold qualifying examinations in medicine, surgery, and midwifery for the purpose of granting a diploma or diplomas conferring the right of registration under the Medical Acts as if the University had been a University in the United Kingdom legally qualified at the passing of the Medical Act, 1886, to grant diplomas in medicine and surgery, and

the provisions of Part 1 of that Act shall be read and have effect accordingly.

8. The Council of the University shall be entitled to choose one representative to be a member of the General Council constituted by the Medical Acts and Section 7 of the Medical Act, 1886, shall be read and have effect as if the University had been expressly included therein. Provided always that the fees for attendance and the travelling expenses of such member payable under Section 12 of the Medical Act, 1858, shall not be paid from the funds of the General Council or of the Branch Council for England until such time as upon the representation of the General Council or of the Privy Council made in the manner set forth in Sections 10 and 19 of the Medical Act, 1886, and subject to the provisions therein contained His Majesty may by Order in Council appoint.

The Council resumed the consideration, adjourned from Wednesday, May 26th, 1909, of the case of Charles William Brown.

Mr. Brown attended in answer to his notice, accompanied by Mr. A. H. Bodkin, counsel, instructed by Mr. W. H. Martin, solicitor, King Street, Cheapside, E.C.

Mr. Paterson attended, accompanied by Mr. Alfred Tarbolton, of Messrs. Brett, Hamerton and Tarbolton,

solicitors, of Manchester.

Mr. Tarbolton stated that in view of the objection which had yesterday been taken, on behalf of Mr. Brown, to the absence of certain witnesses, he had thought it his duty to telegraph to them to attend the Council on this day, and scught permission from the Council to call these witnesses.

Leave was accorded, and Mr. Tarbolton called Mrs. Emily Gertrude Pinder as a witness as to the facts to which she had deposed in her declarations. She was cross-examined by Mr. Bodkin, and re-examined by Mr. Tarbolton.

Mr. Tarbolton called Nurse Elizabeth Greenwood as a witness as to the facts to which she had deposed in her declaration. She was cross-examined by Mr. Bodkin, and re-examined by Mr. Tarbolton; she also answered questions put to her by the Legal Assessor.

Mr. Tarbolton next called Nurse Jessie Gower Taylor as a witness as to the facts to which she had deposed in her declaration. She was cross-examined by Mr. Bodkin, and re-examined by Mr. Tarbolton.

Mr. Bodkin then addressed the Council in a powerful speech on behalf of Mr. Brown.

He then called Mr. Charles William Brown as a witness on his own behalf, and examined him. Mr. Brown was cross-examined by Mr. Tarbolton, and re-examined by Mr. Bodkin. He also answered questions put to him by the Legal Assessor.

Mr. Bodkin called Mr. William Arkless Amery as witness, and examined him.

Mr. Amery was cross-examined by Mr. Tarbolton. On Mr. Bodkin intimating that he had two more witnesses to call, but on question put from the chair it was ascertained that the Council did not desire to hear any further evidence for the defence.

Mr. Tarbolton then addressed the Council in reply. After the Council had deliberated in camera, and strangers having been re-admitted, the President announced the judgment of the Council as follows:—
Mr. Charles William Brown: I have to announce

that the facts alleged against you in the notice of inquiry have not been proved to the satisfaction of the Council.

On motion by the Chairman of business, it was agreed that the Council should meet at 12 noon on Friday, May 28th.

The Council then adjourned.

# TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

MEETING HELD FRIDAY, MAY 14TH, 1909

The President, Dr. W. G. SMITH, in the Chair.

### EXHIBITS.

Drs. O'CARROLL and Purser exhibited a case of PROGRESSIVE BULBAR PARALYSIS

in a man, æt. 56. A year ago the patient first noticed a certain amount of difficulty in his speech. It was very indistinct, but still intelligible. He was now hardly able to protrude the tongue beyond the lips. He had a little difficulty in getting food back, but he did not complain of difficulty in swallowing, except occasionally with liquids. He complained of difficulty in the culty in holding his head up. There was a little wasting of the muscles of the thumb, and of the biceps and triceps of the right side. The knee-jerks of each side were sharp, and occasionally, on stroking the sole of the left foot, Babinski's sign was found.

They also exhibited a case which had been diagnosed as locomotor ataxy. The patient was a young man, act. 23, married at 19, the father of two healthy children. There had been no miscarriages. There was a distinct history of congenital syphilis. About a year ago he got suddenly weak in his left leg, with a pain in his knee. Since then he had had a progressive difficulty in walking. Some two years previously he had "seen double" for a short time. His present condition was that he had not got paralysis of any muscles, but had considerable difficulty in walking, and was very ataxic. Absence of knee-jerks. The pupils contracted neither to accommodation nor light. He appeared to have no loss of sensation in the limbs, but was rather slow in recognising touches on the left leg, especially from the knee down. He had a certain amount of difficulty in passing water; he often had to press, and sometimes it came away without sufficient warning. He had always been a little deaf.

DR. DRURY exhibited two cases of HEREDITARY ATAXIA

Sisters, æt. 11 and 13, who had the disease noticed about three and five years respectively. The younger was the much more advanced case. She stood fairly well with the feet apart, but could not balance at all with her eyes closed. The elder girl had sometimes a slight shaking of the hand, which was only noticeable when watching closely. There was no sensory disturbance, or disturbance of the sphincters. The eye-symptoms were variable. In the younger girl there was slight nystagmus, but some days it was absent altogether. In both cases there was a total loss of knee-jerks. The limbs were well nourished. The younger girl showed well-marked lateral curvature, and both feet were getting flat. She had a systolic murmur heard near the apex; and at the base of the heart she had a loud systolic murmur when lying down, which disappeared when she sat up. The day following the observation of the latter murmur it was exactly the reverse—that is, it was absent when lying down, and present when erect; it varied from day to Sisters, æt. 11 and 13, who had the disease noticed down, and present when erect; it varied from day to day. Her sister had the same. When they came to hospital they were very thin, but they had grown fatter, and better in colour after a couple of months on arsenic.

Dr. DRURY also exhibited a case of

Dr. Drury also exhibited a case of interpretation of the patient had not noticed anything peculiar about his condition, except that he was not a very powerful person. There was anything peculiar about his condition, except that he knew he was not a very powerful person. There was great thinness and want of muscle everywhere. There was no actual atrophy, but he took it that it was still in an early stage. Such cases were usually met with in groups, but there was no history of such in the in groups, but they was a sould not find anything present case. Although they could not find anything in the way of thoracic disease, still he had extremely marked myxædema. His grasp was feeble, but he had quite well-marked knee-jerks.

Dr. T. G. Moorhead read a paper on

GROCCO'S TRIANGLE,

giving his observations on the subject for some years

past.

Dr. KIRKPATRICK said he had looked for the sign during the past two years, and had endeavoured to demonstrate it. He could sometimes demonstrate it demonstrate it. He could sometimes demonstrate it to his own satisfaction, but he had often failed to do so to others looking on. It was in cases of small effusion that the sign was of particular value, and it was in such cases that it was very difficult to elicit it.

The President said that, short of post-mortem evidence, some mystification hung over the subject. It took ten ounces of fluid to produce recognisable physical signs, and in cases of large effusion the sign

was hardly necessary.

Dr. MOORHEAD, in reply, said he was an advocate of early removal of fluid, an dendeavoured to demonstrate it. In three of the five cases in which he did not get the sign he also demonstrated fluid, but he had not been able to demonstrate the relationship between the size of the triangle and the effusion.

Dr. Peacocke read a paper on a case of "Glioma of the Spinal Cord" in a girl, zet. 11.

# CORRESPONDENCE.

### FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Mry 30th, 1909.

EPISTAXIS.

BLEEDING from the nose in certain persons, and especially the aged, is Nature's safety valve, and should be respected or at most controlled by gentle plugging; too brusque compression has been known to be followed by an attack of apoplexy, to which the patient succumbed.

It is however, frequently necessary, under other conditions, to have recourse to firm plugging of the offending nasal fossa in order to arrest the hæmor-

Many different methods have been practised to this end, all more or less disagreeable to the patient. Perhaps the most simple and the most effectual would be as follows:—A thin strip of absorbent wool about an inch and a-half wide is wound firmly two or three times around the point of a pencil or penholder; the pencil is withdrawn leaving a cone of wool about two inches long in the hand, and this plug is steeped in some hæmostatic solution (oxygen water, antipyrine, ferripyrine, etc.), or in pure water. The liquid swells the plug, which is then pressed firmly so as to flatten it as much as possible; it is still moist, long, flat, and a little stiff, of conical form, rendering it easy to pass into the nose. It is inserted horizontally, penetrating its entire length along the septum.

The free extremity of the plug is once more wetted an inch and a-half wide is wound firmly two or three

The free extremity of the plug is once more wetted with the hæmostatic solution, imbibing by capillarity the whole of the plug, which swells up, gently compressing the mucous membrane and effectually obstructing the orifice. A second small plug closes the aparture and the residual plug closes the aperture, and the patient is advised to hold his head slightly bent forward for about an hour to enable the blood to coagulate against the plug. After 24

hours the plug may be withdrawn.

According to Dr. Borde, these plugs seem to be well supported by the patients and produce no irritation of the mucous membrane.

#### TARSALGIA.

Pain in the heel, although by no means a rare affection, has been neglected by the majority of text-books, and yet it is very tenacious and rebellious to all medical treatment, and the patients suffering from this affection get discouraged and drag out a painful existence, for the infirmity, although presenting no external signs, deprives them almost completely of the power of locomotion, walking being so painful.

Vincent of Algiers recommended somewhat recently a very simple surgical treatment of the affection.

The ætiology of tarsalgia is somewhat varied: this malady, which may attack one foot, but more frequently the two feet, was noticed for the first time as far back as 1785 by Swediaur, who ascribed it to blennorrhagia, and in reality this is a frequent cause. Rheumatism, and sometimes gout, have produced it, and perhaps certain infectious diseases. But there is another cause which has been overlooked, viz., traumatism.

According to Dr. Vidal, tarsalgia may be divided into three classes: Inflammation of the serous bursa under the heel; osteitis of the os calcis, accompanied by hyperostosis.

In 13 cases observed by Jacquet, the presence of osteo-fibrous rheumatism of blennorrhagic origin with a certain degree of deformity of the bone was noticed.

Bonnet relates the case of a patient who suffered from excessive pain in the two heels after an attack of blennorrhagia. Radiography revealed the presence of a small bony excrescence under the aponeurosis of each heel.

The third class comprises a fibrous and neurotic form of tarsalgia without deformity which may be produced by the action of certain toxines secreted by infectious agents or by irritation provoked by chronic contusion, as might be observed in subjects whose profession or trade necessitates long standing, by which the adipose cushion of the heel is mechanically compressed or, still better, by a fall on the feet. It is in this last group that Vincent's operation succeeds.

A large incision is made down to the os calcis through the tissues of the heel, curettage of the fibro-adipose tissue suppressing the fibrous network in which the nerve filaments are strangulated; if the bursa is found to be inflamed, it is removed.

The second class seems to be amenable to medical

treatment: rest in bed, massage of the painful region. turpentine baths, ignipuncture down the back.

The turpentine bath recommended by Balzar is as

follows:-

Black soap emulsion and 6 oz.
Ess. of turpentine
However, if improvement was slow to manifest itself, an operation (curettage of the bone) should be tried.

CIRRHOSIS OF THE LIVER.

During the first period (hyperactivity) sedative treatment should be prescribed: Milk diet, laxatives (sulphate of soda, r dr., taken every morning for a week, in a glass of hot water); at night, cold compress wrung out, over the liver and covered with oil silk. Calomel in small doses, 1/5th gr., daily for eight days. The following eight days:—

Arseniate of soda, 1 gr. Water, 10 oz.

A tablespoonful twice a day.

At the period of atrophy, the milk may be replaced by feculents: potatoes with a little butter and salt, macaroni, meal of cereals, etc. Before each of the principal repasts a tablespoonful of:—

Iodide of potassium, 1 dr. Sulphate of strychnine, ½ gr. Water, 10 oz.

And

Benzoate of soda, 5 gr. Phosphate of soda, 10 gr. Jaborandi powder, 2 gr.

For one wafer; to be taken three hours after each

If ascites be present:-

Phosphate of soda, | āā 30 gr. Theobromin,

For three wafers, to be taken at an interval of one hour between each, and repeated during three days.

Vinegar of squills, digitalis or calomel in diuretic does might be tried.

doses might be tried :-

Calomel, 2 gr. Sugar, 10 gr.

For one powder, one to be taken every four hours, without exceeding, however, four in the day.

Such is the treatment advocated by Prof. Robin, of cirrhosis of the liver.

# GERMANY.

Berlin, May 30th, 1939.

AT the Verein für Innere Medizin, Hr. Heubner gave an address on

THE DIFFERENTIAL DIAGNOSIS OF THE ACUTE AND EXANTHEMATOUS DISEASES.

He laid stress on the importance of an exact diagnosis in the acute exanthematous diseases for the patient, for his immediate and his more remote surroundings,

and for the public.

As regarded differential diagnosis in the anteexanthematous stage, special difficulties were presented by those forms of disease in which a lengthened period of latency was a characteristic. Here there were irregularities in the stage of incubation, and even capable physicians were often led astray by them. It is true that these irregularities have been rendered less obscure by conclusions that have been drawn regarding the serum diseases, for which we are indebted to v. Pirquet. According to these conclusions the stage of incubation does not originate from the fact that the poison must first develop in the system, but for the reason that the antigen of the poison engages in a combat with the poison. This assumption is proved by the behaviour of the precipitins, the appearance of which corresponds with the outbreak of the disease, and which could not be proved to be present a short time before. According to this it is easy to understand that an early appearance of the exanthem corresponds with an earlier subjugation of the antigens by the poison. Bacterial examinations regarding streptococci in the prodromal stages of measles and scarlatina which the speaker had carried out had revealed nothing useful as to the differential diagnosis, as both in measles and scarlatina streptococci could be found, so that they could not be specific for both the diseases.

As regarded differential diagnosis in the exanthematous stage, there were the rare cases in which measles were mistaken for small-pox and vice versa. In measles there were occasionally large pock-like nodules, and an exanthem not unlike measles was also

seen in small-pox. Sometimes it was very difficult also to show the difference between measles and scarlatina.

Further, the exanthems of measles and scarlatina confounded with other exanthems. Here the morbilloid exanthems played a special rôle. especially those that appeared after taking certain medicines. From a point of view of differential diagnosis is here to be mentioned that on some part of the body or other an exquisite urticaria-like rash will be visible. The morbilloid exanthem of the infant at the breast causes a good deal of difficulty, even before the sixth month; as contrary to the general assumption that the infant is immune as regards exanthematous diseases before the sixth monthof life, we sometimes see them appear even in the earliest months. Finally, measles frequently appearswith a rash that has a rötheln character, and without the characteristic different mode of invasion.

Scarlatinoid rashes more rarely cause confusion. There is that which is called by some authors the 4th disease, a disease with a scarlatinoid rash and a course resembling rötheln. This disease is really not course resembling rothern. Inis disease is really not scarlatina, but a freak of rötheln. According to others there had been rötheln on to which scarlatina had developed, but there had been free desquamation previously. So much is determined: that rötheln not unfrequently runs a scarlatina-like course; and the different exanthems may sometimes be seen on different parts of the body at the same time. In a case recorded a patient is said to have had rötheln, and four weeks later developed the 4th disease. Against this is to be borne in mind that relapses of rötheln not unfrequently occur with an appearance different from the first attack. In any case the assumption of the 4th disease is not to be rejected until we know more.

And now still another, the 5th disease has made its appearance; it is described as allied to the two first diseases by an absolutely identical course, the so-called erythema infectiosum. It differs distinctly in the character of the rash, which in the face resembles erythema exudativum, whilst on the other parts of the body it has a scarlatina-like appearance. There is further to be pointed out the simultaneous appearance of two acute exanthematous diseases in one and the same child. Thus, according to Viennese authors, there is in measles a special disposition to scarlatina. The malignant scarlatina cases are said to be always cases of such mixed infection. (Pospischill.)

Scarlatina is also said to supervene on rötheln, and also on varicella. Finally, according to Viennese authors, scarlatina is liable to supervene on serum disease. Here it may certainly be observed that the distinction of the two exanthems is very difficult.

In vaccinia a measles-like rash is frequently seen. The diagnosis "generalised vaccinia" is often incorrect. The latter is wide spread over the whole body, easy to be distinguished from the varicella rash. We are far behind in exanthem diagnosis for the reason that we do not know the causal poison. The attempt to effect the complement separation by scarlatina antigen was successful—but unfortunately the same effect was brought about with measles. Perhaps the precipitine method will eventually show results.

# AUSTRIA.

Vienna, May 30th, 1909.

HÆMOPHILIA.

At the Gesellschaft der Aerzte Mautner showed a patient who had suffered for 4½ years with constant bleeding from the gums. This repeated bleeding commenced after the extraction of a molar tooth, and in spite of all efforts to check it would continue for threedays at a time. He obtained the normal serum of the horse from the Institute and injected 20 ctms., which immediately checked the hæmorrhage. The following day a slight oozing of blood appeared, when another 20 ctms. of the serum were injected. Since then no appearance of hæmorrhage has been observed, but on the 28th day after injection an erythema, re-sembling erythema multiforme, appeared over the

whole body. Teleky referred to Prof. Biedl's anaphylaxia by saying that the injection of the serum produced other changes in the organism, as he had found the blood after injecting animals lost its power of coagulation in the space of three weeks. He be-lieved the serum had the power of checking hæmor-rhage, but after three weeks the treatment would have to be repeated. Paltauf remarked that the loss of coagulation was only one phenomenon in anaphylaxia which Biedl and Kraus had observed in the dog, but the experiments were so few in the human subject that the therapeutic value of the serum was as yet very doubtful.

Goitre and Endemic Cretinism.

Kutchera, from Graz, gave the members an exhaustive account of the treatment of goftre and cretinism, which has been undertaken during the last two years by the State. This experiment was initiated by Prof. Wagner in 1907, in Styria, where the disease is endemic. This was conducted from 37 stations in the country, but the patients were treated in their own homes, free of charge, with 0.3 of a gramme in tabloid form; this has cost the Government 3,500 kronen. Treatment was commenced early and very few above the age of leaving school were treated, the eldest being 26 years. All cases of idiocy and the deaf and dumb were excluded, while the rachitic had phosphorus and cod-liver oil in addition. Each received one tabloid per day, but where they were badly borne, three in the week, with excellent results. In 1907 one hundred and eight thousand tabloids were used. In one year and a half 1,011 cases were treated, of these 761 in 1907, and the following year 250. Only 25 cases were unable to take the treatment. In 1908, 608 were still under treat-

Increase of growth in all the cases was very marked, and appeared to run parallel with the other symptoms, with the exception probably of the idiotic and deaf and with the exception probably of the idiotic and deaf and dumb, who increased in weight, but all the other symptoms remained stationary. The pure cretin is not an idiot, as his intelligence and hearing may be weak, but not destroyed. In 440 of the cases 10 per cent. rose to normal manhood; 18 or 4 per cent. slightly below this, while 377 or 85 per cent. rose above the normal. In 143 children below the age of 6 improvement was observed within a few weeks; the enlarged tongue, running of saliva, cutaneous secretion. larged tongue, running of saliva, cutaneous secretion, eczema, and the large gland were notably improved. At the beginning of the treatment it may be observed that a few of them diminished in weight and appeared to fall off, but after a short period there was rapid to fall off, but after a short period there was rapid improvement in the temperament, genitals, teeth, intelligence, speech and hearing. In 677 of the cases examined, 290 or 43 per cent. seemed to be in excellent condition, 329 or 48 per cent. were not so good, while 58 or 9 per cent. had made very slight improvement.

Hochsinger said his experiments were equally successful on the cretin and congenital myxedema. The

question remains: Shall it be necessary to continue the thyroid substance in congenital cases? Are our experiments too recent to give an opinion?

CANADA. Toronto, May 1909.

MEDICAL JOURNALISM IN CANADA.

Among the many problems engaging the medical profession in Canada at present, one of the most urgent is that relating to the medical press. The present state of first-named, any of these journals has any serious scientific standing. In fact, they are subscribed to partly on account of the local professional news they contain and partly for more personal reasons. As a consequence the clientèle of each journal is a very confined one, and no single one appeals to a very large

circle of readers. Indeed, it is probable that each of the three London weekly medical journals reaches an audience considerably more extensive than any Canadian journal. There is, it will be noticed, no Canadian weekly medical journal in existence. This lack has been keenly felt of late years, and an active body of physicians, prominent among whom is Dr. McPhedran, of Toronto, have made many attempts to remedy it. The most obvious course would seem to establish a journal under the auspices of the Canadian Medical Association, and this body has actually agreed

There are, however, more difficulties in the way than might at first sight appear. First is the question of support. It is gravely doubted whether a sufficient number of practitioners would subscribe to either the Association or to the journal directly to ensure the financial success of the venture. The distances separating the different parts of Canada are so large that the interests in common between Quebec Winnipeg, for instance, are very slight, especially as mutual reciprocity between the provinces is so restricted. Therefore, for local medical news each district prefers to rely on its local journal, and for scientific literature on British or American publications. In the next place it is doubtful whether there is enough material to fill such a journal. The great majority of medical men in Canada, even in the large centres, are engaged in general practice, and the number of those who undertake any scientific research or who make original observations is very few. As a result the output of scientific work in medicine is strikingly small, and such as it is is sent to British, or more often to American journals. This state of affairs is, of course, likely to alter as the country gets more settled and developed, but such changes take place slowly. Still, the advent of a weekly Canadian medical journal cannot be long delayed, and it may be expected within a very few years at the longest.

CANADIAN MEDICAL SOCIETIES.

In the matter of medical societies, Canada is more happily placed. Besides the Canadian Medical Association, which holds an annual meeting on the lines of that of the British Medical Association, several of the provinces have an association, which also meets once a year. There are a considerable number of medical societies in the smaller towns, as Halifax, Quebec and Hamilton. One has recently been established. Mished in Winnipeg, with three sub-sections. The Montreal Medical and Surgical Society has for many years been noted for its activities. The Ontario Academy of Medicine is perhaps the most ambitious. It owes its inception largely to the stimulus of Professor Osler, who on several occasions advocated the merging of the local societies into one Academy, as has been done in London to form the Royal Society of Medicine. This was finally accomplished a year ago, and the Academy took possession of the building in and the Academy took possession of the building in Toronto, formerly occupied by the Ontario Medical Library Association. There the nucleus of a good library has been begun, though it is confined almost entirely to books and journals in the English language. The Academy has six sections, one each for Medicine, Surgery, Pediatrics, State Medicine, and Gynæcology, and one for Ophthalmology, Rhinology, Otology and and one for Ophthalmology, Rhinology, Otology and Laryngology. Each section meets, as a rule, once a month, when cases are shown, papers are read, and demonstrations given. Once a month, also, a general meeting is held, at which an address is given by some distinguished visitor, usually American. The meetings are held at the rooms of the Academy in Queen's Park, except the Pediatric meetings, which, for the sake of convenience, take place in the Children's Hospital. The Ontario Medical Association meets this present a Toronto from June 1st to 2rd. At the final year at Toronto from June 1st to 3rd. At the final stance Professor Osler, who is now on a visit to this Continent, is to read an address.

THE CANADIAN MEDICAL CURRICULUM. There is at present much activity in Ontario in connection with the reorganisation of the medical curriculum in the University of Toronto. Since the appointment last December of Dr. C. K. Clarke as Dean of the Medical Faculty a great deal has been

accomplished, and it is certain that in the future the

training at this University will be greatly improved, so that it will achieve a higher scientific standing than has hitherto been the case. The re-building scheme of the General Hospital has been taken up afresh, the connections between the Hospital and University have been made more intimate and perhaps more cordial than before, and a general plan has been outlined and practically accepted for future working. There is every hope that the new hospital may begin building in the coming fall, and an excellent site near to the University has been secured. It is rumoured that Dr. Cecil Leathes, of London, has accepted a professorial position here, and that he will take up his duties in the coming session.

# FROM OUR SPECIAL CORRESPONDENTS AT HOME.

### SCOTLAND.

CRIGHTON ROYAL INSTITUTION, DUMFRIES .- The sixty-ninth annual report of this asylum has lately sixty-ninth annual report of this asylum has lately been issued; it is of interest as being the first from the pen of Dr. Easterbrook, the newly-appointed Physician Superintendent. The total number of cases under treatment during 1908 was 1,034, the average daily in residence being 852—an increase of 32 over the preceding year. The death-rate was low, 6.4 per cent. of the average resident population; nearly half the deaths were due to brain disorders, and only 9 per cent. to pulmonary tuberculosis. The ratio of insanity to the population of Dumfries and Galloway is, according to the 45th Lunacy Blue-Book for Scotis, according to the 45th Lunacy Blue-Book for Scot-land, slightly above the average. Investigation of the causes of the mental breakdown among the patients admitted showed that the constant factor is a nervous constitution, inherited or acquired, and that the so-called exciting causes of insanity—worry, shock, illness, overwork, alcoholism, etc.—are accidental factors, inasmuch as they are insufficient to light up an attack in those with stable nervous systems. In Dr. Easterbrook's experience no person becomes of unsound mind without previously exhibiting evidence of an unduly nervous constitution, inherited or acquired. This evidence may be derived from the occurrence of morbid nervous or mental manipulations among the relatives of the patient, or, more important, from the patient himself, as afforded by the signs of a nervous physique or physiognomy, by the existence of some congenital nervous or mental defect, or by the occurrence of some neurosis or psychosis during former life, or by previous addiction to excesses, or by the possession of an abnormal or a typical disposition and temperament. The last is, in Dr. Easterbrook's experience, the most frequent as well as the most delicate or subtle sign of an unstable nervous system.

During the year the sanatorium was fully occupied, and every advantage was taken of it for extending the sanatorium treatment to all forms of mental affection. Many improvements have been effected during the year—verandahs have been added to the hospital wards, fresh precautions against fires have been taken, an additional villa residence for private patients has been provided, and the accommodation for the patients belonging to the lower private and parochial departments has been improved. The principal change which Dr. Easterbrook has inaugurated is in the direction of developing the pathological department. A thoroughly equipped laboratory for clinical and scientific research is being looked forward to with the greatest interest by the medical staff, and will help the latter still more than hitherto in the diagnosis and treatment of the patients' maladies. As the success of the laboratory depends not so much on the walls and appliances as on the efforts of its workers, the highly important question of the personnel of the Crighton laboratory staff is still under consideration. Appended to the report are the reports of the Commissioners on Lunacy, which testify to the excellence of the management of the Asylum.

Since Dr. Easterbrook's report was issued arrange-

ments have been made for the appointment of Research scholars to work in the new laboratory. The scholar-ships are worth £250 a year, and may be renewed. Applicants must have shown their competence to do research, and have had training in the necessary methods.

# LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE CAMPAIGN AGAINST UNOUALIFIED DENTISTS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—It is much to be deplored that Dr. Duke should have published the letter under the above heading which appears in your issue of May 26th. If Dr. Duke were an obscure and unknown man, the mischief would be less. He seems not to have realised that his letter is as good an argument against medical law reform for which you are striving as it is against prevention of practice of dentistry by men falsely pre-tending to be qualified. The fitting of artificial teeth is very rarely a purely mechanical operation. There are always questions of surgery of remaining teeth to be considered; and, however skilful be the mechanic, he cannot help inflicting unnecessary suffering and injury if he have not at least the knowledge of surgery that is called for in the licentiate in dental surgery. The injury that an ignorant practitioner of dentistry must inflict in a large proportion of cases renders a minimum qualification essential. What would Dr. Duke say if it were argued that some surgical instru-ment makers were skilful, and could adapt and apply a pessary with a success equal to or greater than the qualified specialist. No law will ever be passed to prevent artificial teeth-makers from carrying on their trade, and no law will ever be made to prevent un-qualified men from practising in any other department of medicine or surgery, so long as they do not falsely pretend to be qualified. The public are guarded against such deception in the case of lawyers, dentists, and veterinary surgeons, but not in the case of doctors. For this reform you, Sir, are now working. Dr. Duke's letter and utterances of that kind cannot be said to be helpful to the cause.

I am, Sir, yours truly,
M.R.C.S., L.D.S.

May 26th, 1909.
[Dentistry does not directly involve questions of life and death, but the issues it includes are sufficiently serious. If Dr. Duke will inquire he will find that there are vast numbers of people, especially among the less wealthy classes, who are going about with mouths to the last degree septic owing to the fact that artificial teeth have been fixed in over a mass of necrosed and suppurating roots by ignorant or dishonest artificial teeth makers. The trade of the bone-setter, which Dr Duke wishes put an end to, is not much more harmful than this, and practically does not involve so great a risk to life. Septic mouth of the kind I refer to is in itself a cause of mortal disease, and constitutes a determining factor in bringing about a deadly result in many maladies which otherwise might be made amenable to treatment.]

MEDICAL RESEARCH DEFENCE SOCIETY. To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,-The Committee of the Research Defence Society have asked me to send you a copy of a letter which has been sent to the Secretary of State for Home Affairs, as follows:

To the Rt. Hon. Herbert J. Gladstone. Sir,-We desire, as members of the Research Defence Society, to call your attention to the fol-

lowing facts:

The Royal Commission on Experiments on Animals was appointed in 1906. It began to hear evidence in October of that year, and during 1906 and 1907 a great amount of evidence was given by many witnesses. So long ago as December 18th, 1907, the Commissioners decided that they did not

wish for any further evidence, but they met once more, on March 25th, 1908, to hear evidence on a special point. Apart from this one meeting in 1908, it is now nearly a year and a half since the Commissioners ceased to hear evidence, but they have not yet issued their report.

We are of opinion that this long delay is con-

trary to the public interest, and is likely to pre-judice the public mind. We, therefore, beg you to exercise all your influence to hasten the issue

of the Report.

We remain, Sir, yours faithfully, The letter has been signed by the Earl of Cromer, President of the Society; the Hon. Sydney Holland, Chairman of Committee; the Duke of Abercorn, Lord Avebury, Lady Bliss, Lord Robert Cecil, Lord Cheylesmore, Sir Savile Crossley, the Hon. Walter Guinness, Sir Edwin Ray Lankester, Sir Frank Lascelles, Mr. Frederick Macmillan, the Earl of Malmesbury, Sir Patrick Manson, the Duke of Montrose, the Dean of St. Patrick's, Lord Rothschild, Mrs. Scharlieb, Professor Starling, Sir Reginald Talbot, Sir Frederick Treves, the Duke of Wellington, and the Bishop of Winchester.

I am, Sir, yours truly, STEPHEN PAGET,
Hon. Sec. Research Defence Society.

70 Harley Street, W., May 26th, 1909. The letter has been signed by the Earl of Cromer,

# AUSTRALIA FOR THE SONS OF MEDICAL MEN.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—Some time ago you were good enough to allow me to call attention in your columns to the opportuni-ties which life on the land in Australia offered to lads and young men, and to point out what excellent avenues to this the various Government Agricultural training in scientific and practical agriculture in all its branches can be obtained at a cost of from £20 to £30

a year, including first-class board and lodging.

After finishing the course, fertile land in a district
of good rainfall can be obtained on reasonable terms, for either sheep, wheat, dairying, fruit growing, or mixed farming. As a result of this many doctors mixed farming. wrote to me, and some have already sent out their

I am at present in London, and will be glad to correspond with any others, or arrange an interview with them.

I have visited most of these colleges myself, and so can speak from experience. I hope to make arrangements for a lantern lecture on the Australian Agricultural Colleges, to be given at Belfast when the British Medical Association is meeting there, and to be present myself, to see any medical men who may desire further information.

My address for the next two months will be the Royal Colonial Institute, Northumberland Avenue, London.

I am, Sir, yours truly, RICHARD ARTHUR, M.D., President, Immigration League of Australasia.

AN URGENT APPEAL FOR ASSISTANCE. To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—May I ask you courteously to publish the accompanying list of donations in answer to the "appeal" which you kindly inserted in The Medical Press and Circular " for May 19th, 1909?

I am, Sir, yours truly, John W. Moore.

# **OBITUARY.**

CHARLOTTE LOUISA ELLABY, M.D.PARIS, L.S.A.

WE regret to announce the death of Miss Charlotte Louisa Ellaby at her house in Harley Street, at the

age of 55

Miss Ellaby graduated M.D. in Paris in 1884, and in the autumn of that year, on the recommendation of Mrs. Garrett Anderson, she went out to Bombay to join Dr. Edith Pechey (the late Mrs. Pechey-Phipson), first at a temporary hospital, and afterwards as second physician to the Cama Hospital for Women and Children on the opening of the institution in 1886. Here Miss Ellaby worked most successfully, not only in the special eye department which she inaugurated,

but also in a very large out-patient department.

After some years of this work in Bombay Miss Ellaby resigned her appointment and returned to this country for the purpose of devoting herself entirely to ophthalmology. In order to have a registrable British qualification she passed the examination of the Society. of Apothecaries, which had recently been reopened to women. In 1900 she accepted an invitation of the committee of the New Hospital for Women to organise an eye department there, and was appointed the first ophthalmic surgeon. Here she worked until failing health, fought with great courage, compelled her resignation three years ago. In the winter of 1894-5 Miss Ellaby had returned to India for a few weeks to perform a double-cataract operation upon the Ranee perform a double-cataract operation upon the Ranee of Jamnagar. The operation was successful; but it was partly to this visit to India that Miss Ellaby attributed her subsequent ill-health. At the time of her death she was consulting ophthalmic surgeon to the New Hospital for Women, lecturer on ophthalmic surgery to the London School of Medicine for Women, and a member of the Faculty of Medicine of the University of London the University of London.

# THOMAS FREDERICK HOPGOOD, M.R.C.S., L.R.C.P.

WE regret to record the death of Dr. Thos. Frederick Hopgood, of Sunderland. Dr. Hopgood had a stroke last July, but had seemingly recovered from the effects of it. He had reached the age of 62.

Perhaps the chief work of the deceased was associated with the Sunderland and Durham County Eye Infirmary, to which patients from all parts of the North of England went to be treated. He practically founded the present institution, and his enthusiasm Infirmary work also occupied much of the time and skill of Dr. Hopgood, and he was there on the day prior to his death, to all appearance as well as usual. Dr. Hopgood studied at University College, London, was a Fellowes gold medallist and silver medallist in surgery, medical jurisprudence, and pathological anatomy.

# OPERATING THEATRES.

# ST. THOMAS'S HOSPITAL.

PYOSALPINE AND GENERAL PERITONITIS. - MR. EDRED CORNER operated on a woman, æt. 32, who had been admitted for severe abdominal pain and vomiting, which had come on a fortnight previously, after a long walk. She had worn a ring pessary for years, and her menstruation had been very irregular. On admission the abdomen was found to be soft, but there was great tenderness in the lower part. There was an indefinite swelling in the left iliac region. The operation was performed on the fifth day after admission. The temperature was subnormal and the pulse 72.

An incision was made in the middle line. The intestines were found to be red and injected. A double pyosalpinx was present, and on the left side there was pyosaipini, was present, and on the left was also a cyst containing foul-smelling pus. Both tubes were removed, the broad ligaments ligatured, and Douglas's pouch drained per vaginam and by the abdomen. The appendix was also removed as it was included in the adhesions; it was the seat of considerable inflammation, which, Mr. Corner remarked, was secondary to the salpingitis.

Mr. Corner said the diagnosis of the case had originally been that of acute peritonitis, but when the patient was examined per vaginam a large pyosalpinx was easily felt on each side. The uterus was fixed by the adhesions. He pointed out that it was always more difficult to separate a pyosalpinx on the left side owing to the adhesions between it and the rectum, adhesions which seem almost to surround the gut; the separation is much less difficult on the right side, where, however, the surgeon has sometimes to deal with the appendix, as in the present case, in which he considered the safer plan was to remove the

appendix, which was much inflamed. The after history of the case was peculiar; there was subsequently a free discharge through the vagina and from the abdominal wound. Fever continued for nearly seven weeks, with cough and expectoration. No bacilli of tuberculosis were found in the sputum. There was dulness at the bases of the lungs; aspiration was negative. The patient ultimately recovered.

Mr. Corner considered that the infection must have travelled from the pelvis by the ascending colon to above the liver, between it and the diaphragm, giving rise to a sub-diaphragmatic abscess, which had discharged through the lung. This infection, he thought, must evidently have travelled up before the operation for pyosalpinx. There had been no suspicion of it at the time.

#### News in Brief. MEDICAL

Prevalence of Measles.

MEASLES still continues to cause a number of deaths. In the 76 large towns to which the official returns In the 76 large towns to which the official returns relate the general death-rate last week was 14.7 per 1,000, having in the previous three weeks been 14.5, 14.1, and 13.7. In some towns, however, the rate was much higher, i.e., West Bromwich, 21.5; Tynemouth, 22.4; Coventry, 23.4; Wolverhampton, 28.9. Wolverhampton's death-rate from measles alone was 6.5, and Coventry's 2.6 from the same cause. Two deaths from small-pox were registered in Bristol. London's death-rate from all causes was 14.0 per 1 000, including 52 rate from all causes was 14.0 per 1,000, including 53 deaths from measles.

International Congress of Applied Chemistry.

THE seventh International Congress of Applied Chemistry was opened on May 27th at the Albert Hall by the Prince of Wales. Over two thousand scientists by the Frince of wales. Over two thousand scientists were present, including a number of lady chemists from Russia and America. Germany is represented by Professor O. N. Witt, of Charlottenbourg, Dr. Delbrück, Dr. Dinsberg, and others; France by M. Gautier, M. Sabatier, and M. Béhal; and delegates came not only from every European country, but even came not only from every European country, but even from China and Japan. In the evening the Lord from China and Japan. In the evening the Lord Mayor entertained Sir William Ramsay, the President, and the various delegates at the Mansion House. The Ambassadors of the foreign countries represented at the Congress and the members of the Government were invited. Afterwards a reception was given to the delegates at the Foreign Office by Mr. Lewis Harcourt, on behalf of the Government.

#### Death Under Anæsthetics.

THE circumstances surrounding the death of George John Cornish, aged 66 years, were investigated on May 17th by Mr. P. H. Childs, Deputy Coroner for Portsmouth. The widow, Catherine Cornish, stated that her husband had been under operations at the hospital for cancer. He had not been able to take solid food since August. On the 14th inst. deceased was prepared for an operation at the hospital, and when a couple of drops of chloroform had been administered to him by Dr. Pope deceased expired before the actual operation was commenced.

Deceased had previously been examined according to the rule. Artificial respiration was resorted to for half an hour, but without avail. Dr. Pope had made a post-mortem examination, and attributed death to syncope. The Deputy Coroner remarked that the jury had received

evidence that the operation was necessary, and he was satisfied that the anæsthetic had been given in a competent manner. The jury returned a verdict in accordance with the medical evidence, and the foreman remarked that the jury were satisfied that the anæsthetic had been properly given.

#### Medical Examination of School Children in Fife.

THE sub-committee appointed by the Fife County Council to meet the County Education Committee in connection with the scheme for the medical examina-tion and supervision of school children met in the County Hall, Cupar, on May 21st, Sir Ralph Anstruther, Bart., presiding. It was pointed out that while the County Council

had practically given consent to Dr. Dewar, the county medical officer, being the responsible officer for carrying out the scheme, Dr. Dewar was also the medical officer for the District, and that the District Committees would have to be approached on the subject.

Mr. Wm. Low stated that they would make the necessary representation to the District Committees, and he submitted a memo. on the subject, showing what quid pro quo they proposed for Dr. Dewar's services.

Before finally agreeing to the terms of appointment the secretary was instructed to communicate with ex-Provost Alexander on the subject.

Commemoration Day.-Proceedings at Livingstone Col-

COMMEMORATION Day, on Wednesday last, drew a very large and influential company to the College at Leyton.

The Very Rev. Dr. Butler, Master of Trinity College, Cambridge, presided, and the Principal, Dr. C. F. Harford, made an introductory statement showing the great progress which had taken place since Professor Macalister gave the inaugural address in the first premises of Livingstone College 15 years ago. Public opinion had entirely changed as to the necessity of medical training for missionaries, and it was now regarded as an absolute necessity for missionaries to have some medical knowledge.

The Master of Trinity, in his address, referred to Ine Master of Trinity, in his address, referred to Livingstone's challenge to Cambridge University, in which he said: "I go to Africa to make an open door for commerce and Christianity; do you carry out the work which I have begun, I leave it with you." This challenge has led to the going forth of Bishop Mackenzie and others who had sacrificed their lives in the cause of civilisation, these valuable lives might have been saved if they had had the advantage of modern training such as was given at Livingstone College.

Dr. Alexander Macalister, after referring in very kind words to the Principal, who had been one of his old pupils at Cambridge, stated that he had watched the College with great interest, from its commencement, and though doubts had been expressed as to the wisdom of the training given, he thought that these wisdom of the training given, he thought that these doubts had long since been laid aside, and as an old medical teacher he had thorough confidence in the course of training given at the College. From his experience in many parts of the world, specially in Syria and in China, he believed that it was a necessity for a missionary to be able to render simple medical aid to the natives, and in the absence of qualified medical aid it was most important that ordinary missionaries should have elementary medical training as is given at Livingstone College. He hoped that before long some such training would be regarded as an absolute neces-

br. Stein, the well-known Asian explorer, related how he had consulted many eminent surgeons both in India and in England, and they all said that nothing could have been better than the conservative surgery which had been carried out by Mr. Schmitt, and which had left him far greater use of his right foot than he

had ever ventured to expect.

Mr. W. McAdan Eccles, F.R.C.S., moved a hearty vote of thanks to the chairman and speakers, which was seconded by Dr. Price. The meeting terminated with the Benediction, which was pronounced by the

Master of Trinity.

#### NOTICES TO CORRESPONDENTS. &c.

Correspondents requiring a reply in this column are par-ticularly requested to make use of a Distinctive Signature or Initial, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much con-fusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two valumes each year begin on January lat and July 1st respectively. Terms per annum, 21s.; post free at home cr abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

CONTENUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

Dr. Leslik Thorne Thorne's letter is unavoidably held over

DR. LESLIE TRORKE TRORKE'S letter is unavoidably held over until our next.

COL. F. H.—Owing to the closure of the office on Bank-holiday, your "Notes" were received too late for insertion in the present

COL. F. H.—Owing to the closure of the office on Bank-holiday, your "Notes" were received too late for insertion in the present number.

DR. HARDY.—The work is by an American author, and is published in New York.

EXCELEGIOS.—As has been repeatedly pointed out in our columns, the term "ophthalmia" has no scientific significance, and is now obsolete. Iritis, of rheumatic origin, which formerly was called rheumatic "ophthalmia," is now called rheumatic iritis, and, similarly, "purulent conjunctivitis," in childhood, has displaced the antiquated term "ophthalmia neonatorum."

L.R.C.P. (Manchester).—The case was tried in the High Court in February and dismissed. Yours would appear to run on parallel lines, and we should advise you to leave law alone.

DR. J. Russell. will find a detailed account of the arrangements, hotel and lodging accommodation at the forthcoming Congress at Buda Pesth in our issue for April 28th.

H. G. N. (Sunderland).—Your experience is by no means novel, we have often pointed out that the proper course, if consulted upon a case in which civil proceedings are contemplated, the amount of fees for examination, and for appearance in court on first and subsequent days, should be clearly set forth and agreed upon. Further, we advise that unless the solicitors and their clients are men of the best reputation, it is well to insist upon fees being paid before taking any further action—at any rate, before going into the witness-box. Crede experto.

W. A. S.—Tar preparations have been to a great extent superseded by more elegant remedies, such as oil of cade, creolin, and oyllin. Some day, however, it is possible that the virtue of homely tar as an external remedy may be rediscovered. It is diuretic and mildly antiseptic, and is sometimes useful in gastro-intestinal catarrh. At one period tar water enjoyed an enormous vogue as a specific for a host of maladies—in France it was the famous Eau de Goudron.

Scotties Practitioner.—Yes, you may do so, provided you have the necessary ever for the reception o

# Routine Disinfection.

# A Suggestion to School Medical Officers.

The dust from the floors of elementary schools has been declared by the Lancet to come second only to that collected from the floors of public-houses, in the number and malignity of the disease germs it contains. The only practical, effective defence against this constant menace to the health of whole communities lies in the routine employment of a germicide of recognised standard strength. This is provided in

## Jeyes' Special Fluid - Cyllin -

which, by the simple device of appointing sanitary monitors in each class-room, can be applied to the floors of a whole school in a few minutes. The cost of systematic disinfection is so trifling as to be reckoned in farthings. Its employment has the endorsement of the Local Government Board, the Scotch Education Department, the President of the British Medical Association, etc., and it has already

been adopted by numerous School Boards throughout England and Scotland,

With a view to the prevention of infectious disease the Bucks Education Committee had the floors of twenty-five schools sprinkled nightly during the past twelve months with a solution of Jeyes' Special Fluid, the attendance in these schools being compared with that of the remaining schools in which the process was omitted. The official report shows an improved attendance in the disinfected schools sufficient to earn additional grants amounting to over £50, while the entire cost of disinfection for the twelve months was less than £30.

"To cleanse a school-room properly it is necessary to destroy the germ-life as well as to remove the visible dirt." (Scotch Education Department Memorandom, November, 1907.)

To the new School Medical Officers an exceptional opportunity is presented. They are in a position to preach the gospel of health with authority, and it will reflect immensely to their credit if they can point, as a result, to the continuous banishment of serious epidemics from districts under their charge.

Particulars of the most efficient method of disinfecting schools can be obtained free on applying to

#### Notes and Comments.

The Church and "Healing."

THERE has been a good deal of talk the last few months about associating the Church of England with the medical profession in a sort of mutual bond for the treatment of the

sick, the main idea apparently being that when the doctor thinks a little more faith and a little less medicine is required, he should apply to the parson to second his endeavours. For our part, we should advise the Church to enter on no such task, and we are quite sure the medical profession will not. Each body has its own defined sphere, and each does best when it confines itself within its own The truth appears to be that a certain section of the Church is being drawn towards Christian Science, falsely so-called, and the promoters of the new movement are seeking to provide counter-attractions within the pale of orthodoxy. The fact is, that in a large heterogeneous body like the Church of England there are sure to be, among the rank and file of sensible folk, a proportion of ecstatic individuals who are agog for something new and sensational, and the reputed "cures" of Christian Science, and assertions as to the early practice of some of the Christian Churches, have induced them to provide a healing system of their own, in which credulity bulks largely and from which reason modestly retires.

A Modern
"Hospice."

As the outcome, apparently, of this movement a hospice, it is announced, has been opened near Regent's Park for the practice of spiritual healing under the auspices of the Church.

The modus operandi consists in adopting the old formula of prayer and laying-on of hands, together with that anointing with oil which the Peculiar People lay such stress on and which brings so many children's bodies to the coroners' courts. According to a published interview with Mr. Hickson, the president of the hospice, the principles of this institute differ in some essentials from those of Christian Science and faith-healing, but we do not gather in what the difference lies. At any rate. the body to whom the hospice belongs are known as the "Society of Emmanuel," and it is asserted that institution is the first of its kind established in connection with the Church of England. sort of place it is may be judged from the following account given by a lady member of the Society:—
"Only the other day a distinguished cleric of the Church of England visited the hospice and told us how some time ago he was afflicted with cancer. The doctors abandoned all hope of cure. Then friends induced the patient to call in Mr. Hickson, who arrived on the morning of a day on which the sufferer was to undergo an operation. Mr. Hickson prayed with him and anointed him, followed by the laying-on of hands. In the afternoon the surgeon arrived and made his examination. He was greatly surprised. 'This case puzzles me,' he was did. 'There is the mark of a new wound, but the cancer has gone.' The cleric in question is now perfectly well. . . ." We would be satisfied to leave such pernicious nonsense alone, if it stood by itself, but when it is foisted on to the public with the hall-mark of the Church, we ask the Bishop of London if he is content to allow such a blot to stain his diocese?

The Profession
and "Indiscretions."

An article, purporting to be written
"By a Physician," appeared in the
Manchester Evening Chronicle of
May 28th, in which the question is
gravely discussed as to whether a

medical man is justified in giving a false certificate to shield a patient from the consequences of his own wrong-doing. The case quoted is one, said to have happened in Germany, in which a telephone girl, laid aside as the result of "indiscretion," was certified by her medical attendant to be suffering from influenza. The lie was found out, and the doctor prosecuted for giving a false certificate, with the result that he was condemned to a short term of imprisonment. In this country there is no law that we know of which would render a medical man liable under the same circumstances unless the certificate was a statutory one, to which a specific penalty for falsification was attached, as, for instance, in the case of death certificates. The writer goes on to argue that it is an open moral question whether such deception is right, and to insinuate that doctors are in the habit of sparing their patients who are suffering from over-indulgence in alcohol by saying that they are "run down and require a few days' rest." He further brings in the question of professional secrecy, and announces that the question is one of much perplexity.

Secrecy and Lying. It is grievous to think that any respectable journal should publish an article in which it is even suggested that it is an open question whether doctors are justified in lying, and we

make bold to say that we do not believe the article was written by any more substantial member of the profession than the now-proverbial "Harley Street Specialist" of the yellow press. No question of professional secrecy arises at all when an employee asks his medical man for a certificate. The certificate is given to him and he can use it or not as he wishes. No medical man can be bound to state, for the gratification of his patient's employer, what the patient is suffering from. But any

medical man who tells a lie and says a patient has influenza when he knows he is suffering from anything else, deserves to be expelled from the profession for disgraceful conduct, and we have little doubt but that he would be if such a case were brought to the knowledge of the General Medical Council.

#### LEADING ARTICLES.

THE NEW MILK BILL.

THE Milk Bill recently presented to the House of Commons by Mr. John Burns is undoubtedly a measure possessing features of great value, but, so far as we have been able to judge, it is, nevertheless, open to considerable improvement. Should our surmise be correct, it is to be hoped that the opinion of public health experts will be authoritatively ascertained, and the Bill amended, before it passes into its final stages. The importance of the purity of the milk supply of the nation is so vital that it would be a thousand pities were a safeguarding measure of the kind introduced by the President of the Local Government Board to be weakened by avoidable defects. The point to which most medical men will at once turn, in view of the advances of recent years, is the steps taken to exclude tuberculous milk. In the present Bill great pains have been taken to empower medical officers of health to follow up infected milk to its origin and to exercise more or less personal control on the spot, and at the same time to set in motion the local authorities. However excellent this plan may be in theory, we cannot help feeling a little doubtful how it would The urban medical officer of work in practice. health is, for the most part, a busy man, loaded with many responsible duties. In order to control the milk supply of his district, he must be provided with an ample laboratory and with a special staff of inspectors. Supposing him to have found time to surmount the first great obstacle of identifying the source of origin of a certain infected milk, the further demands upon his time and energies are considerable. The dairy centre implicated may be at any distance, say, twenty, fifty, or a hundred miles away. He has to travel thither and find out, if possible, the particular farm from which the infected milk came, or he may have to inspect several suspected farms. His visit is made with a veterinary inspector, and he has to inspect the cows it may be fifty or a hundred or more—in order to detect the tuberculous animals. At this stage he can only direct that none of the milk from these cows shall be sold for human consumption, and that he may enforce with an interim order from himself, pending an order from his own Sanitary Authority prohibiting, under penalty, any such sale. The new departure involved in this proceeding opens up various possibilities that require careful consideration. Under its agency we find some medical officer of health acting independently in the district of another medical officer, and we feel bound to say that we view the prospect thus disclosed with some apprehension. Mr. Burns provides further machinery for control in an Order from the Board of Agriculture, whereby the possessor of any cow suffering from tuberculosis of the udder, indurated udder, or other chronic diseases of that

organ, or from the emaciation of tuberculosis, shall give notice to a sanitary inspector or a police constable. The local authority of the district shall examine the animal, and if found tuberculous may order it to be destroyed, provided its value does not exceed £30, in which case its destruction can be carried out only with the consent of the Board of Agriculture. There is a further clause in the Bill imposing a penalty on any person who knowingly exposes for sale for human consumption tuberculous milk, unless the latter has been sterilised. Without going exhaustively into the points of the measure at this stage, a few obviouscriticisms may, nevertheless, be made with advantage. First and foremost, we are at present inclined to think that Mr. Burns has-to use a homely phrase-got hold of the wrong end of the stick in more ways than one. Instead of attempting to control the tuberculous milk-always a complicated and difficult prblem-he should adopt the more logical step of controlling the tuberculous cows. If it be found necessary for the medical officer of health to go into other districts in his quest for the origin of the infected milk, let him hand the tuberculous cows and dairies over to the local sanitary authority, to be dealt with then and there. Co-operation between urban and rural authorities we believe to be absolutely necessary as regards milk control, but that is a very different thing from a confusion and multiplication of administrations. If the examination of milk for tuberculosis germs be necessary, should it be not performed at the farms or dairies of origin rather than thrown upon the shoulders of consumers? Then there is the fatal flaw of leaving the inspection of farms to local authorities composed of persons whose interests are not furthered, to put it mildly, by a stringent administration of their duties. A system of central inspection and control, with the cost of extermination of tuberculous cattle thrown upon the imperial and not upon local taxpayers, is, in our opinion, essential to the framing of a solid and enduring Act. As regards the sale of tuberculous milk, it is obvious that the average dairyman can know nothing at all about the matter, and will evadepenalty on the condition "knowingly" appended tothe offence. It is to be hoped that the Association of Medical Officers of Health and other bodies of medical men will lose no time in discussing the various aspects of the Milk Bill before it passes into law. Mr. Burns will do well to get some authoritative medical advice and opinion outside that of the Local Government Board before the last. word is said in the House of Commons on his. present proposals, which we are happy to think, in spite of various defects, constitute a vigorous and, in some ways, a most commendable attempt in the right direction.

#### CURRENT, TOPICS.

The Taxation of the Motor-Cars of Medical Men.

We are glad to learn that at last a definite protest has been instituted by medical men against the injustice of taxing not alone their motorcars, but the petrol which they use in them. As we report in another column, a special meeting of the Motor Union Committee of Medical Motorists was held the other day, and was largely attended. The meeting resolved to approach the Chancellor with a view to securing a rebate of three-halfpence per gallon on petrol used by medical men. This is a step in the right direction, but even more important than it would be a protest from the British Medical Association or the Irish Medical Association. We understand that the latter body, at its annual meeting to be held this week, will have the matter before them, and we trust that some steps will be taken to bring the views of the Association before the Chancellor. In any action it takes, the Irish Medical Association should remember that medical men in Ireland are now being called on to pay not alone a petrol tax, but another entirely new tax for the car itself, as, up to this there has been no such thing as a carriage tax in Ireland. The result is that the medical owner of a single ten-horse motorcar in Ireland, who drives, say, five thousand miles a year, will have to pay five guineas a year taxation, while his neighbour, who may have numerous horses and carriages, pays nothing. It is to the interest of the public that medical men should be brought to use motor-cars, and this is hardly a good way to encourage them to do so.

#### Strawberries and Strawberry Litter.

Now that the strawberry season is at hand, we once again draw attention to a serious danger to health connected with the growing of the fruit for market. As the berries reach maturity their stalks bend beneath the weight until they reach the ground. In order to protect the fruit from the soil the growers are in the habit of putting down litter. The right and proper thing to use for the purpose is straw, but we regret to say that a pernicious habit has of late sprung up amongst market gardeners of using manure in any degree of rotten-This method is obviously dangerous to health, as it contaminates the strawberries with multifarious microbes, some of which are likely to be of a kind deleterious to the consumer. It is a fact well known to growers that strawberries that have been thus exposed are extremely apt to become decayed and mouldy. The method is undoubtedly economical, inasmuch as it saves the laying down of manure for the next crop. It is of so undesirable a nature, in our opinion, that the local rural authorities should be empowered to put a stop to it in the interests of the public health. It is simply a commonplace to observe that the origin of many summer maladies is obscure, and that not a few of them may probably be ascribed to contaminated fruit. It is surely not asking too much that the public should be protected against the dangers inseparable from the filthy practice of bringing ripe strawberries into direct contact with rotten manure.

#### Condition of Irish Factories,

It seems as if the North of Ireland were gaining a very scandalous notoriety for its neglect of all matters pertaining to the public health. The sanitary administration of Belfast and the condition of the primary schools in Belfast and the County Down have both been before the public of late years in a way not creditable to the people of the North of Ireland, who are usually regarded as

hard-headed business folk. The report of the Chief Inspector of Factories, published a few days ago, shows that the condition of many of the factories is as bad as that of the primary schools. Martindale, in her report, mentions that in two large towns factories were found in which the sanitary accommodation for women was most unsuitable, especially with regard to the want of privacy. In both cases notices were met with the assertion that the accommodation complied with the requirements of the standard laid down by the local authority, and in one case the factory had been visited by members of the Public Health Committee, who had expressed themselves to the occupier as being quite satisfied with the arrangements in question. Other cases are quoted in which conditions dangerous to health were due quite as much to the neglect of the sanitary authorities as to that of the proprietors. In many cases there was no heating of the work-rooms, and Miss Martindale found rooms with a temperature in March of 45°, where the air contained 3.28 parts of CO<sub>2</sub> per 1,000. When prosecutions were instituted, there was the greatest difficulty in gaining a conviction, or nominal fines were inflicted. Instances are also quoted of grave breaches of the Truck Act, and of improper conditions under which young children are employed. The whole subject is one deserving the serious consideration of the public, for, as Miss Martindale remarks, until opinion is roused the children of the Irish industrial classes will remain weakly and undersized, the high death-rate will continue, and the children will grow up as illiterate as their innate brightness and cleverness will allow.

#### The Future of Medical Education in Ireland

THE "Statutes of the National University of Ireland, and of its Constituent Colleges," as published last week, are of interest to the medical profession, in that they lay down the lines on which medical education in the new University is to proceed. We abstract the principal points in another column, but here we have to express our general satisfaction with the scheme drawn up by the Dublin Commissioners. In addition to the traditional medical and surgical degrees, the University is to grant degrees of B.Sc. and D.Sc. in the subject of Public Health. The constitution of the faculty of medicine in the Dublin College seems to be satisfactory. There are to be eleven professorships, and six lectureships, the minimum salary for a lectureship being £50, and the maximum for a professorship £800. Cork, too, is to have an adequate medical school, with ten professorships and five lectureships. The medical school in Galway has always been a difficulty, on account of the inadequate funds at the disposal of the College, and the lack of sufficient hospital material. No improvement is made under the new scheme, and we can hardly expect the school to hold its own against its better-equipped rivals. One teacher is still expected to deal with the entire subjects of anatomy and physiology, and no provision is made for the teaching of pathology! The College hardly seems wise thus to starve its medical school and to spend considerable sums in the teaching of dead languages. On the whole, however, medical education in Ireland

ought to be much improved under the new conditions.

The Proper Diet of Mankind.

DR. F. GOWLAND HOPKINS, speaking at the Royal Institution last week, is reported to have asked the question: "What would be the most efficient food of man?" The answer to that question he gave us by saying that the most sensible person is the cannibal, as he gets precisely the quality and proportion of the foodstuffs needed by the human body by taking them directly from that organism. In consuming his own kind he eats exactly the right stuff. As an instance, Dr. Hopkins quoted a Heidelberg experiment in which a dog was fed with dog-flesh, and was thus enabled to do with a much smaller quantity of protein than when fed with protein derived from any other source. The nearer species are allied, he argued, the less difference is there between the chemical constituents of the tissues of individuals, and therefore the less the work thrown on the processes of digestion and conversion, and therefore ape must be more nourishing to man than is beef or mutton. We cannot allow this cannibalistic theory to go forth as the dernier cri of science on the question of diet. The chemistry of food is a very vague state, and theories of dietaries are as numerous as they are conflicting. One thing, however, is certain, and that is that animals are divided into herbivora, carnivora, and omnivora. We can, therefore, no more agree that it follows that human flesh is the best diet for man than that horse-flesh is the best food for a horse. "Dog don't eat dog" is a good old proverb, and it will take several generations of physiologists to persuade us that the proper diet of mankind is man.

Egypt and Malaria.

THE remarkably outspoken utterances of Sir Ronald Ross at the Royal Institution recently attracted a good deal of public notice. It is interesting to compare with what was then said a question asked of Sir Edward Grey by Mr. Ramsay Macdonald in the House of Commons shortly before the Whitsuntide recess. The Foreign Secretary was asked if Mr. H. C. Ross had to leave the Egyptian Sanitary Service owing to his zeal for stamping out malaria; and if that was not the reason, why he had to leave. The answer was that Mr. Ross was never in the Egyptian Department of Public Health as a permanent officer, and he resigned his temporary post when he heard that the Director-General was not prepared to give him a permanent appointment in Cairo. It is, of course, a well understood farce in public life that the head of a department, in answering a question, gives, not his own view of the circumstances-for in ninety-nine cases of a hundred he has never heard of them before-but the reply prepared for him by the permanent officials. A flood of light bearing on the real circumstances is shed by a letter from Mr. H. C. Ross to the Times, of June 2nd. Mr. Ross points out that he was a surgeon in the Royal Navy, with, at least, the ordinary hopes of preferment and pension in the Service, but that, through the introduction of his brother, Mr. G. H. Ross, Medical Officer of Health

for Port Said and the Suez Canal, he was brought into contact with Sir Horace Pinching, Director of the Egyptian Public Health Department. seems that Sir Horace offered Mr. Ross a temporary post in the Service, with the reversion of the next vacancy if he gave satisfaction, and on the strength of these representations Mr. Ross resigned his appointment in the Navy and went into the temporary appointment offered. The work specially assigned to him was the initiation and carrying-out of an anti-malarial campaign, which he undertook con amore, and with some success. Soon after, Sir Horace Pinching resigned, and recommended to his successor that the vacancy thus caused should be filled by Mr. Ross's appointment. The new Director-General seems to have been a man of the old type who regarded the destruction of mosquitoes as a frivolous amusement and not as hygiene, and he appointed an Army medical officer to the vacant position. Mr. Ross consequently had nothing to do but to resign. We are giving the ex parte statement and nothing else, but we can only say that if the facts are as stated, the Egyptian Department of Public Health would seem to be conducted on principles at variance-let us say-with common decency. We trust that Sir Edward Grey will cause a special inquiry to be made into the circumstances for the honour of the country.

#### Holidays and Health.

During the past ten days it has occurred to many medical men to ask themselves whether the benefits to the community arising from occasional general holidays at all counter-balance the injuries. It is a general maxim that an occasional change does one good, and that holidays are a necessity. It is true that in the stress of modern city life, few people can continue to work year in and year out without a break, and maintain constant good health. For most of us holidays are, if not a necessity, at any rate something we cannot well do without. This is, however, quite a different contention than to hold that a day seized from business and devoted to some equally arduous pursuit of a less accustomed nature is fraught with good results to health and happiness. As a matter of fact, the strenuous bank holiday is often as injurious to the golfer or the man who, starting from his office-stool, takes a twenty-mile walk, as to the artisan's child who is made sick in honour of the holiday. It is said that as a people we take our pleasures sadly. It would be equally true to say that we take them foolishly. We make too much of a business of them; we are not content to idle, and for a brief holiday idling is probably best.

#### Irish Schools.

On many occasions during the past few years attention has been drawn to the scandalous condition of the Irish primary schools in matters concerning ventilation, sanitation, and heating. The subject was again brought before the public a week or two ago by a deputation of the Women's National Health Association which waited on Mr. Birrell. In his reply to the representations made to him, the Chief Secretary admitted the indefensibility of the present system, but was, at the same time, careful not to commit the Government to any

promise of help. It would appear that at present there is no public fund, either local or general, available for the upkeep or improvement of school buildings. In many cases, according to Mr. Birrell, the very fuel for heating the school is supplied out of the miserable salary of the teacher-a salary less than that of an artisan. The position taken by the State is incomprehensible. On the one hand it proclaims compulsory education. On the other, it leaves school buildings in such a condition that attendance in them is injurious to the health of children. We hold that the child's health is of infinitely more importance than his school education, and until the State insists on sanitary school buildings, it is doing a grave injury to the public health by demanding school attendance.

#### PERSONAL.

THE fourteenth annual meeting of the Guy's Hospital Ladies' Association has been held under the presidency of Princess Christian of Schleswig-Holstein.

A MEETING of the Socialist Medical League was at the Holborn Restaurant, London, on June 3rd, when Dr. J. Robb opened a discussion on "The Nationalisation of the Medical Profession." Twentynine persons were present.

THE Annual Welsh Medical Dinner will be held at the Criterion Restaurant, London, on June 15th, when the chair will be taken by Dr. D. C. Lloyd Owen, of Birmingham. The date has been selected for the Birmingham. The date has been selected for the convenience of those who will be visiting London for the National Eisteddfod.

DR. EDWARD LIVEING has resigned the registrarship of the Royal College of Physicians of London, which he has held for twenty years. The Council of the College has placed on record its appreciation of the devotion and energy with which Dr. Liveing discharged the duties of his office during so many years.

THE members of the Council of the Royal College of Surgeons of England who retire this year by rotation are Mr. A. W. Mayo Robson, Sir W. V. atson Cheyne and Mr. R. Clement Lucas. We understand that Mr. Harrison Cripps and Mr. W. W. H. Jessop, of St. Bartholomew's Hospital, intend to offer themselves as candidates at the next annual election.

A NUMBER of retired Indian medical officers, who could not attend the annual dinner in London, dined in Edinburgh on May 28th, at the Caledonian United Service Club, Sir Alexander Christison, Bart., occupying the chair. Among those present were Surgeons. General Bidie, C.I.E.; Turnbull, K.H.S.; Sinclair, C.S.I.; and Hay. The guests included Dr. Allan Jamieson, P.R.C.P.; Mr. Cotterill, P.R.C.S.; Colonel Corker, R.A.M.C., P.M.O.; Sir Halliday Croom, and Dr. MacBride.

MR. GRAFTON ELLIOT SMITH, Professor of Anatomy at the Government School of Medicine, Cairo, has been appointed by Manchester University to the Chair of Anatomy, in succession to Professor Young, resigned. Professor Smith was educated at the University of Sydney, New South Wales, and was appointed successively Demonstrator in Anatomy and King Travelling Fellow in the University of Sydney. He continued his work at Cambridge, and obtained a Fellowship of St. John's College, and was University Demonstrator of Anatomy.

Dr. D. EDGAR FLINN, Medical Inspector under the Local Government Board of Ireland, and Dr. W. J. Howarth have been elected Fellows of the Royal Sanitary Institute.

THE annual meeting of the Birmingham Medical Benevolent Society was held on May 25th. Dr. Malet, the retiring President, was in the chair, and he was supported, among others, by Sir James Sawyer and Sir Thomas Chavasse. The eighty-seventh annual report states that the invested funds of the society amount to £15,940, with a balance of £120 98. 7d. at the bank. Sir Thomas Chavasse was elected l'resident and Dr. Simon President-elect.

In the annual grant voted by Parliament in aid of scientific investigations into the causes and processes of disease, the President of the Local Government Board has authorised researches by Dr. Theodore Thomson, Medical Inspector of the Board, in conjunction with Dr. Hedingham, of the Lister Institute; Dr. Theodore Thomson and Dr. C. J. Thomas; Dr. Dr. Theodore Thomson and Dr. C. J. Thomas; Dr. Monckton Copeman, Medical Inspector of the Board, and Professor Nuttall, of St. Bartholomew's; Dr. Andrewes; Dr. Savage; Dr. Schölberg and Mr. Wallis, of University College, Cardiff; Dr. Darwall Smith, Physician to the British Lying-in Hospital; Dr. Inman, Pathologist to the Brompton Hospital for Consumption; Dr. J. Hiller, Pathologist to the General Hospital, Birmingham.

SIR RUBERT BOYCE, Dean of the School of Tropical Medicine, who has been visiting the West Indies under the auspices of the Colonial Office, for the purpose of reporting on the present methods of dealing with sickness in these Colonies, returned to Southampton on Sunday last (May 30th) in the Orinoco. The visit was arranged on the suggestion of Mr. Owen Philipps, M.P., Chairman of the Royal Mail Steam Packet

THE National Association for the Prevention of Con-THE National Association for the Prevention of Consumption and other Forms of Tuberculosis is now holding a free Tuberculosis Exhibition for the education of the public, and more εspecially its poorer sections, at the Art Gallery, Whitechapel, and it will remain open until June 19th. On June 2nd the opening address was given by the Right Hon. John Burns M P Burns, M.P.

At the conference to-day "The Treatment of Consumption" will be dealt with by Dr. Arthur Latham, Physician to St. George's Hospital; Dr. Paterson, Superintendent of the Frimley Sanatorium; Dr. Jane Walker, Superintendent of the East Anglian Sanatorium, Nayland; and Dr. H. W. McConnel.

To-MORROW will be devoted to "The Prevention of Consumption," and the papers will be read by Dr. Duncan Forbes, Medical Officer of Health, Brighton; Dr. E. W. Hope, Medical Officer of Health, Liverpool; and Dr. J. Edwin Squire, C.B., Senior Physician to Mount Vernon Hospital for Consumption. Evening lectures are being given at the sumption. Evening lectures are being given at the exhibition, and the lecturers include:—Dr. C. Theodore Williams, Dr. Frederick Rose, Dr. Newsholme, Medical Officer to the Local Government Board, Professor G. Sims Woodhead, Dr. Hector Mackenzie, and Dr. Nathan Raw.

THE Twelfth International Congress on Alcoholisms will be held in London from July 18th to 24th. H.R.H. the Duke of Connaught is honorary president, and! Lord Weardale acting president. On Sunday, July: 18th, the Official Sermon will be preached by the Bishop of Croydon at the afternoon service in St.: Paul's Cathedral.

On July 19th the Inaugural Address will be given-On July 19th the Inaugural Address will be given-by the Acting President, and in the afternoon the-exhibition will be opened by the Dean of Hereford, Chairman of the Conveners, while the evening will be devoted to the official reception. Papers will be read at the Congress by Professor Taav. Laitinen, M.D., Dr. A. Holitscher, Dr. Legrain, and Dr. Stein. British contributes are to be read by Professor Sims Woodhead, M.D., Dr. W. H. R. Rivers, F.R.S., Professor Clouston, M.D., Dr. F. W. Mott, F.R.S., and Dr. R. W. Branthwaite, H.M. Inspector under the Inebriate Acts.

#### CLINICAL LECTURE

#### THE EXTRACTION AND CUTTING OF THE ROOTS OF THE TRIGEMINAL NERVE, AS AN OPERATION SUBSTITUTING THE EXTIRPATION OF THE GASSERIAN GANGLION.

By PROF. JULIUS DOLLINGER, M.D.,

Professor of Surgery at the University of Budapest.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

Gentlemen,—It is most flattering to me to be able to lecture again here (a) on the same subject I selected for my address last year, and which has given rise to such a valuable discussion on the part of members of the Association. Then I dealt with the question of the extirpation of the Gasserian ganglion; now I will endeavour to speak on the merits of the extraction of the nerve roots.

In my former lecture I pointed out that the extirpation of the Gasserian ganglion is dominated by excessive hæmorrhage, and that the obviating of this causes great anxiety. Further, that in some cases even the mere approach to the ganglion causes serious bleeding, which is further increased by the opening of the cavernous sinus when extracting the ganglion. The opening of the sinus occurs almost in every instance, in consequence of the anatomical relations existing between the first branch of the trigeminal nerve, the inner side of the ganglion, and the lateral wall of the cavernous sinus. In order to evade the opening of the sinus, and the hæmorrhage resulting from this manipulation, I have separated—as mentioned in my previous lecture—all the surfaces of the ganglion (excepting of course the inner one) from their surroundings; then I have pulled out from under the tent the root of the trigeminal nerve, and cut the second and third nerve-branches before their exit out of the skull, leaving intact that part of the ganglion which is ingrown into the lateral side of the cavernous sinus, while I removed the lateral parts of the ganglion, together with the stumps of the second and third branches which originate therefrom. In one case I was successful, while in another the sinus opened when the ganglion was excised, thus causing most profuse hæmorrhage. These two cases have taught me to pull away in front the nerve roots independently from the ganglion, as I anticipated in my last year's lecture.

I will now quote a few instances where I have performed this operation successfully. My first patient was an army officer, æt. 35, who suffered from severe trigeminal neuralgia for six years and a half. Four years ago a few nerve branches were resected, but this operation gave only temporary relief. I subsequently operated on April 28th, 1908, having previously ligatured the external carotid artery, the consequence of which was that the excision of the temporal flap and the opening of the skull caused less hæmorrhage than is generally the case. As the middle meningeal artery bled considerably I ligatured this also. Then I separated the tent from the edge of the petrous bone at the site where the roots of the trigeminal nerve enter the scala media, caught the roots in clamps, and extracted them from under the tent, and cut them in a central direction from the ganglion; this latter I left untouched. length of the extracted roots was 31 cm., and their width 6-8 millimetres. I then sutured the wound without any drainage. I should state that imme-

diately after the operation the pupil of the eye on the side operated upon had not contracted, nor did the tension of this eyeball decrease. In several other cases the occurrence of these symptoms has directly followed the operation. (According to Morat, the carotid plexus of the great sympathetic nerve sends a branch to the Gasserian ganglion, which branch contains the dilating fibres of the pupil. Testut, "Traité d'Anatomie Humaine," I., II., p. 778.) With the Gasserian ganglion a piece of this sympathetic branch, too, is removed, in consequence of which the pupil contracts, while if the Gasserian ganglion, and with it the Morat sympathetic branch, remains uninjured, the contraction of the pupil does not set in. Besides the safety of the ganglion, the operation has the undoubted advantage of insuring that the nutrition of the eye does not suffer.

I examined this patient eighteen days after the operation, and found that his skin, cornea, the mucous membrane of the nose and stomach were quite anæsthetic on the affected side, and not hyperæsthetic, as in the cases of Taboulay. On the affected side the sense of taste was wanting on the point and rim of the tongue; the masticating muscles were paralysed, with the exception of the temporal muscle. The patient could masticate on the sound side. The secretion of the mucous membranes and of the lachrymal gland did not undergo any changes. The neuralgic pains have since entirely abated, and on October 5th, that is, after five months, all these good symptoms were unchanged, the patient has resumed his military service and is quite healthy. Thus this case proves that for the cure of a trigeminal neuralgia it is not absolutely necessary to remove the Gasserian ganglion, but it suffices to extract the trigeminal root, as advised by Van Gechuchten. The operation ran so smoothly and was so devoid of difficulties, that it would tempt one to declare it to be without danger, and to believe that we have conquered the many difficulties which surrounded this operation.

Referring to this operation, Dr. Morestin has remarked that the laceration of the trigeminal roots, and by that the separation of the Gasserian ganglion from the central nervous system, is equivalent to the extirpation of the ganglion, and that as it is easier and less dangerous, it is more

advantageous than the latter.

During the last week, however, I had the opportunity of performing the operation twice, and these new experiences have led me to believe that Morestin considers the operation from a too optimistic point of view. In my first case the dura mater was easily lacerated, and as I separated it from the skull it became torn, so that the cerebral gyri became visible, and the careful lifting of these and their exposure aggravated the separation of the trigeminal roots considerably. When finally succeeded in accomplishing this, and could grasp the root, it gave way, and its central end was withdrawn under the tentorium cerebelli, so I could catch only a few insignificant nerve rootlets with the

<sup>(</sup>a) This lecture was delivered before the members of the Surgical Congress in Paris.

aid of my forceps; but at the same time severe arterial bleeding commenced in the deep part of the wound, so that, assuming that somehow I had injured the internal carotid, I instantly tamponaded the base of the skull and ligatured the common carotid artery. I had no opportunity of ascertaining whether I had torn the trigeminal root entirely across or not. After five days I removed the tampons, examined the area of the operation, and found that I had entirely torn away the root; moreover, the same symptoms were manifested as in the previously-described case, where the extraction of the trigeminal root has been done in so ideally successful a manner. The ligature of the common carotid artery did not cause any symptoms. The patient has since entirely recovered.

On the next day I performed the same operation on a woman, æt. 35. Upon lifting of the dura mater, such a profuse, uncheckable hæmorrhage occurred from the Santorinian emissaries, that I was unable to survey the field of the operation, and therefore I could not be sure whether I had torn across the root entirely or not, because the bleeding forced me to tamponade the wound and to close it. As after the operation neither the affected side of the face nor the masticating muscles became anæsthetic, three days after the operation I disunited the wound again, and thoroughly examined the Meckel cave. However, I could not find any trace of the root. The face has since remained unanæsthetic, and the masticating muscles have been in working order.

Thus the first of the three operated cases has given us the lesson that in a favourable case we may easily succeed in extracting the trigeminal root entirely; but the second and third cases have shown that this cannot be taken as a rule, for the laceration of the root in these has revealed certain difficulties which it must be our endeavour to guard

against.

The cases hitherto operated upon, however, have proved that we may cure a severe neuralgia as well with the laceration or extraction of the trigeminal root as with the extirpation of the Gasserian ganglion. In those cases wherein I have extirpated the Gasserian ganglion, I have usually extracted also the nerve root (in twenty-two cases), together with the ganglion. I did not see any harmful consequence from this manipulation. The other less severe consequences may be expected to arise from the extraction of the root itself.

Moreover, it may be that it will be sufficient simply to cut the nerve root between the ganglion and the tent, as advised by Professor Tendrassik. The fibres of the nerve root do not possess sheaths, and therefore it is not probable that they will grow together after dissection. From a physiological point of view, it would be a great advantage, and from the technical point an achievement, if we could cut entirely the strong sensitive root, and so preserve the thin root containing the motor fibres of the masticating muscles.

A physiological advantage of the extraction or dissection of the nerve root over the extirpation of the ganglion is that we leave the sympathetic nerve passing from the carotid plexus to the eyeball, with the mediation of the Gasserian ganglion, untouched; this is done by leaving in the Gasserian ganglion, in consequence of which the pupil does not get contracted, and its innervation remains undisturbed. It is possible that this nerve, as well as the left Gasserian ganglion, it of a beneficial effect upon the nutrition of the eyeball, and that with the relinquishing of these formations the eye

will be less exposed to those trophic changes which

follow extirpation in some of those cases where the patients do not sufficiently take care of their eyes and neglect the surgeon's instructions. On these points experience in the near future will enlighten us. As for the technique, the operation needs as much skill, anatomical expertness and experience as the extirpation of the Gasserian ganglion; it has, however, this advantage over it, that with it we can avoid that bleeding which originates from the cavernous sinus and which follows the removal of the ganglion.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Edmund Cautley, M.D. Cantal F.R.C.P.Lond., Physician to the Belgrave Hospital for Children, and to the Metropolitan Hospital. Subject: "The Treatment of Broncho-Pneumonia."

#### ORIGINAL PAPERS.

# THE ESSENTIALS OF PHYSIOLOGICAL HISTORY.

By DAVID FRASER HARRIS, M.D., B.Sc.Lond., Lecturer on Physiology in the University of Birmingham.

ABSTRACT OF LECTURE III.

The School of Hippocrates, although it knew that wounds of the brain caused paralysis on the opposite side of the body, had no physiology of the nervous system. Hippocrates wrote on epilepsy and hysteria, yet he used "neura" as meaning "sinews." Aristotle, believing the brain bloodless, imagined it secreted "pituita," which entered the nose through the ethmoid bone. Erasistratus of Alexandria, the first to affirm nerves arose from the brain and not from the heart, was also the first to distinguish sensory from motor nerves.

Herophilus, eponymous for the "Torcular," invented the term "calamus scriptorius." Aristotle had placed the soul in the heart, Hero-

philus believed it to be in the brain.

Galen knew almost more of the anatomy of the nervous system than of the vascular. He had notions of separate paths of conduction within the spinal cord, he displayed the brain in five steps of dissection, but he classified the cranial nerves on the basis of seven pairs.

Achillini of Bologna (1463-1512) described the appearance of what we now call the "Fornix" and "Hippocampal region," and saw the lateral

ventricles.

Berengarius (1470-1530) corrected previous errors, particularly that the optic nerves were the first pair.

Vidus Vidius (died 1569) gave his name to the

'Vidian '' nerve.

Vesalius (1540) knew that nerves were only conductors of impulses, and that section of the spinal cord deprived parts of sensation and movement. He knew a good deal about the comparative anatomy of the brain from fishes upward. In particular he could not accept the dogma that the "anterior" ventricle is for sensation, the middle for imagination, the posterior for memory.

Eustachius (died 1574), C. Varolius (1543–1575) and J. C. Arantius (1530–1589) all advanced our knowledge of the cerebral nervous system, Varolius leaving his name in the Pons and Arantius coining "Hippocampus."

The views of Paracelsus on the "archaei," and

of van Helmont on "Blas" were noticed, the latter placing the soul in the pylorus of the stomach.

The notions of Thomas Willis (1621-1675) were reviewed; he thought that sensory images were imprinted on the corpus callosum, the corpus striatum acting as a lens below. Willis was the first person to have any idea of reflex action, he speaks of "animal spirits" rebounding from within outwards in a reflected wave.

René Descartes (1596-1650) elaborated a complete but mechanical theory of neural activities. The "rational soul" he banished to the Pineal gland whence it directed bodily activities after the manner of a "fountaineer controlling the activities of fountains and other mechanical devices, working apparently automatically in royal gardens, grottoes, &c.

Nicholas Stensen (Steno) (1638-1686) had more than glimmerings of cerebral localisation of function. He despaired of the unravelling of the nervous system until a far better method than any he knew of preparing it should be discovered. We had to wait 200 years for this "better way."
Raymond Vieussens' "Neurologia Univer-

salis" (1685) added much to knowledge of the structure of the nervous system. Vieussens was one of the ornaments of the medical school at Montpellier (1641-1716).
Stahl introduced the "anima sensitiva" which

helped physiology no more than his "phlogiston"

had helped physics.

At the beginning of the 17th century, Dr. Harris said, research was branching out in so many different directions that we had the history of discoveries of regions of the nervous system to consider, viz.:—Spinal cord, medulla oblongata, pons varolii, cerebrum, cerebellum, peripheral nerves, including the "sympathetic system" and nerve cells themselves.

Time allowed only to follow the history of knowledge of the spinal cord and reflex action and of cerebral localisation. Boyles, Hales, Descartes all contributed to knowledge of the spinal cord.

Robert Whytt, of Edinburgh (1716-1766) discovered the light iris reflex, and did much for the physiology of reflex action without using the term. Spallanzani, in Italy (1768), and Herbert Mayo, in England (1823), advanced our knowledge of the cord. Sir Charles Bell (1778-1842), a native of Edinburgh, in 1811, made the exceedingly important discovery that the posterior roots conveyed ingoing fibres, the anterior roots outgoing. This "Law" was confirmed and extended by Magendie in 1822. In 1832, Marshall Hall coined the term "reflex nerve arc," and investigated reflex action from the clinical standpoint. He studied the reflex maintenance of tonus. With the subsequent history of this subject the names of Grainger, Schiff, Goltz and Ewald are associated.

Although Cerebral localisation had been vaguely believed in for a long time, until 1870 it was thought that the cortex cerebri was inexcitable to artificial stimuli. Haller (1708-1777) in particular tried every possible stimulus without eliciting any visible effects. The phrenologists held the doctrine of cerebral localisation in so grotesque a manner that the idea fell into discredit.

J. J. Gall (1758-1828) certainly thought the centre for speech was where Broca in 1861 proved it to be, the left inferior frontal convolution in

right-handed people.

Fritsch and Hitzig, surgeons in the Franco-Prussian war, found the cortex cerebri of a wounded man excitable to electric stimulation. Ferrier, before 1876, had confirmed and extended their work.

Later researches here and abroad have abundantly corroborated the doctrine that sensations and movements are represented topographically, or are related to different regions of the brain.

The important contributions of Flechsig, the elder Waller (1850), Helmholtz (1850), Furkinje, Waldeyer, Golgi, Ramon-y-Cajal, and Nissl were very rapidly seviewed.

#### EYE-STRAIN (ASTHENOPIA). (a) By GEORGE A. BERRY, M.B., F.R.C.S., F.R.S.E.,

Consulting Ophthalmic Surgeon to the Edinburgh Royal Infirmary ; Lecturer on Ophthalmology to the Edinburgh University.

In opening a special discussion on this subject, the author observed that he preferred the oldfashioned word, asthenopia, to the newer "eyestrain"; when qualified by such adjectives as nervous, accommodation, muscular, and the like, it conveyed a definite meaning. As a first class of cases in which eye-strain might occur he instanced those which were characterised by a sensation of conjunctival or corneal irritation, and watering of the eyes. This might be produced by reading in an unsuitable light, particularly if the illuminant contained too many of the more actinic rays. In reading out of doors, for instance, the light reflected from the white paper contained an enormous number of these rays. The same was the case with some of the modern incandescent illuminants. Reading in bed was frequently stated to be a cause of weakness of the eyes; it was probably not the position assumed, but the fact that often only the imperfect light of a single candle was used, that gave rise to the sense of discomfort. In cases in which it was desired to protect the eyes from the effects of excess of atinic rays he found London smoked glass perfectly satisfactory. It was formerly the practice to keep patients suffering from eye symptoms caused in this way in the dark for a considerable period. This was an unnecessary severe line of treatment, and also made the eyes unduly sensitive to light.

Turning next to eye-strain from refraction error, he laid particular stress on lid pressure as a cause of headache. Where a patient had astigmatism of a moderate degree, he was able, by compressing the globe with the eyelid, as in the act of frowning, to improve the vision by correcting the error. The effect of pressure with the finger on the eyeball could be made out with the ophthalmometer, and in some cases the effect of lid-pressure in altering the refraction of one axis of the eve could also be demonstrated in the same way. In patients who suffered from headaches due to astigmatism, a history of frowning was often obtainable. It had at one time been supposed that in these cases the refraction error was corrected by an irregular contraction of the ciliary muscle, but, as a matter of fact, this was an error.

In correcting astigmatism he had entirely given up using cycloplegics. Their effect on cases of astigmatism depended entirely on the variations in the size of the pupil they produced, and in their

(a) Abstract of paper opening a discussion at the Edinburgh Medico-Chirurgical Society, June 2nd, 1909. The discussion will be found on page 586.

allowing more of the marginal rays of light to enter the eye than when the pupil was contracted. In another class of case eye-strain was due to failure of the associated movements of convergence and accommodation, whereby, when the eye converged on a point in space, they were no longer accommodated for the same point. In America great attention had recently been devoted to muscular imbalance as a cause of eye-strain. Mr. Berry stated that in nearly every person carefully tested some degree of deviation of the axis of the eyes was present. While it was perfectly easy to keep the eyes parallel in moving them laterally or upward, if they were directed straight forward, without being fixed on any definite object, some degree of divergence or convergence was usually present. He therefore attaches no importance to this abnormality. Marked deviation of one eye upward or downward was, however, in a different category. It was not due to muscular action, but to an anatomical asymmetry of the orbit. It could be corrected by suitable prisms. number of cases asthenopia was due to purely nervous or hysterical causes. These cases were often cured by suggestion or any sudden and strong impression. He had sometimes been able to cure them by subcutaneous injection of distilled water in the frontal region.

In connection with the question of the symptoms of eye-strain, the author pointed out that it was, on the whole, the slighter cases of astigmatism in which by lid pressure, etc., it was possible for the patient to improve his vision, that headache occurred. If the refractive error was too great to be improved in this way, no eye-strain occurred. Mr. Berry advised that all cases of migraine should have the eyes examined, because in some the remedying of any refractive error cures the condition. considering the class of headache most often due to ccular defects, he thought that relief was most likely to be obtained from glasses when the headache definitely followed using the eyes. He thought that in some cases headaches were really due to gout; in old people this did not often escape notice, but in children it was more liable to do so.

#### HIGH FREQUENCY CYTOLYSIS FULGURATION OF CANCER.

BY J. A. RIVIERE, M.D.PARIS, Rédacteur-en-chef des Annales de Physicothérapie

In the paper I read before the Congress of Medical Electrology and Radio-therapy (Paris, July 27th—August 1st, 1900), I called the attention of medical men to a main and primordial fact—namely, that localised high frequency currents exercise an elective, destructive and specific action on cancer cells.

I added, in this first stage of my investigations, that the application of effluves and sparks was followed by rapid elimination of the neoplastic tissues, and that any loss of substance so caused was rapidly filled up. I asserted, moreover, that even if the knife was required for the removal of large tumours, it was not less indispensable to employ high frequency "scintillation" to the surgical wound in order to disinfect it, to drain it in a certain degree in a specific manner, and finally to prevent recurrence of malignant neoplasms.

Finally, I have maintained since 1900 that these therapeutic measures were the only ones which could be rationally brought forward in the treatment of inoperable tumours, and since that time I have spoken of the necrosis of plastic tissues exposed to the action of sparks-of the disappearance of induration, of ædema and of glandular enlargements, of the appearance of an abundant inodorous laudable serous discharge, which has taken the place of the original fœtid ichor-of the analgesic, cicatrising and vitalising action of this

electric modality on the process of repair, which in my subsequent works I have called "sclerogenous processus" ("Annals of Physical Therapy," January, 1904). I also noted the remarkable amelioration in the general condition, which kept time with the excellent local modifications.

From the preceding, is it not correct to conclude that I was the first to think of utilising high frequency currents for the treatment of malignant tumours? In my communication to the Congress of Medical Electrology and Radiology (Paris, July-August, 1900) I expressly called attention to the thick sparks obtained through the medium of Oudin's resonator, and I concluded by saying:—

"They begin by producing a thermo-electro-chemical action (a) which has the effect of eliminating the neoplastic tissues, and, if we admit the parasitic theory, of destroying the micro-organisms and their toxins; and, in the second place, they cause a tropho-neurotic curative action which restores the vital processus to its normal state."

Evidently it would not be a question of employing thermo-electro-chemical action to eliminate large thermo-electro-chemical action to eliminate large tumours for which surgical ablation would be indi-cated, but the surgical measures should be supplemented by preventive and curative treatment directed against the possibility of recurrence.

High frequency currents, and more especially monopolar effluves (b) emanating from Oudia's resonator seem to exercise this action by modifying the vitality of the fresh regions contaminated by the incisions of the surgeon (c) after having disinfected and drained them. This special mode of applying electricity seems at present to be one of the only therapeutic methods worthy of trial in cases of inoperable tumours.

In my 1900 treatise, speaking of the electro-thera-peutic cure of local tuberculous affections, I clearly pointed out the rapidity with which loss of substance was filled up; the strangely æsthetic character of cicatrisation, etc. I admitted the hypothesis of a defective nervism to explain the inordinate proliferation of the neoplastic cells and the feeble resistance they showed to the mono- or bipolar effluves and sparks.

In my communication to the Academy of Medicine Obscimber 8th, 1903), "Physico-therapy as applied to the Cure of Cancer," I showed a series of cases which had been benefited by the combined action of high frequency sparks and effluves combined with Röntgen rays; at the same time I spoke of the elective action of these two agents on the neoplastic cell and of the advantage of utilising them in concurrence and alternately during the course of treatment.

Dr. A. Darier, the well-known ophthalmologist, sent me a lady who presented growths which, under examination by the eminent histologist, Jean Darier, at the laboratory of the College of France, had been recognised as alveolar sarcomata of Billroth. patient was cured whilst under my care of multiple tumours of the neck, of the orbital cavities and of the mediastinum by the combination of high frequency sparks and effluves with the Röntgen rays. This was the first case of malignant tumour, the iagnosis of which had been verified by histological

(a) The thermic action must not be eliminated. I consider it even beneficial. It causes no inconvenience to the patients. I have seen cases which, under the sole influence of the analgesic action of high-frequency scintillation, have tolerated on the most tender spots the longest and most highly nourished brushes and sparks for about twenty minutes. The necrobiotic action of the spark and of the effluve, which I was the first to point out in a paper read to the Academy of Medicine in 1903, is most manifest in such a case.

(b) In subsequent works I have often made use of the word "effluvation," to indicate the high-frequency "conflagration" brought about generally by effluves and sparks. The barbarism, "etincelage," "sparking," I have avoided. When surgical measures have been complete, effluvation is sufficient; when the surgeon has leftneoplastic masses or infiltrated tissue, sparks are more efficacious. Here, to speak truly, we have not a question of operative "chniqua" as has since been stated, but a simple one of appreciation which the electro-therapeutic expert and the least experienced surgeon are able to understand. The effluve is the spark reduced to a spray; to obtain it, it is sufficient to remove the electrode to a greater distance; its striking action is more marked and penetrates more deeply because its voltage is higher. Short sparks on the contrary have a high amperage.

(c) The expression "solution of continuity caused by the operation" indicates that according to the pleasure of the surgeon, effluves and sparks can be utilised during all the steps of the operation.

examination, being cured by physical agents; it was certainly a case which carried conviction.

In the same communication to the Academy, I brought forward, amongst others, a case of epithelioma of the tongue, one of ulcerated carcinoma of the breast, two of uterine epitheliomata, in one of which the disease had recurred; in all these cases complete results were obtained by the same method.

Since then many patients, the subjects of malignant tumours, have been placed under my care and all have derived benefit from high frequency in the form of

effluves and sparks.

In the "Annals of Physico-therapy" (January, 1904), In the "Annals of Physico-therapy" (January, 1904), "Analytical Thoughts on Cancer and its Treatment by Physical Therapeutics," I gave a long explanation of the cytolytic action of high frequency sparks and effluves; "of their tropho-neurotic power, which is the cause of the subsequent retrogressive mortification, the effect of vaso-motor contraction and obliteration of the precessity of pushing the treatment. arterioles . . . of the necessity of pushing the treatment as far as elimination of the necrobiotic products reabsorbed by the organism." . . . In this work I added: "That ordinary surgery very often does not reach the limits of the infection, in spite of very free incisions, and that it is necessary to pursue the morbid cells into their last strongholds. The curative influence of high frequency sparks and effluves and of the X-rays," I went on to say, "shows itself to be far more precise and far more distinct, and therefore it precludes failure and recurrence, by reaching on the one hand, owing to their power of penetrating the deeper tissues, the generating roots of the tumour, which are really the abettors of the increase of the growth, and by neutralising, on the other hand, those formidable toxins which are gradually elaborated in the inmost and latent depths of the anatomical elements." ments." Subsequently I remarked: "The method in question seems to restrain the genesis of all newlyformed tissues which have been engendered by a vicious and disordered activity of the cellular anatomical elements.'

I returned to the consideration of the same questions a: "My Views on the Cancer Microbe"; "A Conin: "My Views on the Cancer Microbe"; "A Convincing Case of the Cure of Deep Sarcoma by Physical Therapy" (Annals of Physico-therapy, January, 1905); "High Frequency Effluves and Sparks for the Rational Cure of Malignant Tumours" (Gasette des Hôpitaux. November 14th, 1907); "High Frequency Effluves and Sparks in the Treatment of Malignant Tumours" (French Congress of Medicine, Paris, October 14th—16th, 1907); and, finally, in: "High Frequency Effluvation and the Cure of Neoplasms" (Second International Congress of Physico-therapy, Rome, October national Congress of Physico-therapy, Rome, October

13th-16th, 1907).

In all these papers I spoke of the difference that existed in the action of the mono- and bipolar sparks and effluves-of the appropriate electrodes for each case-electrodes of different metals for ionic action which we have not yet been able to differentiate; condensating electrodes, of varied shape and capacity, which allow the application to be made to the deepest parts of cavities. I showed the necessity of having recourse to high frequency and Röntgen ray applications at more or less close intervals during cicatri-sation in order to prevent recurrence, but not to the exclusion of the application of effluves and sparks to the wound made by the knife at the time of operation. I spoke also of the absolute necessity of attending to the diathetic arthritic condition of the patient, of looking after his food and his general hygiene; finally, I brought to light the great importance of assisting the elimination of the necrosed parts with reference to their return in bulk to the general circulation.

High frequency effluves, both large and small, exercise an evidently destructive action on the neoplastic cells which, under their influence, rapidly disaggregate; this is proved by an early increase in the size of the cancer wound; the healthy tissues, on the contrary, show a determined resistance to the effluves, and only become disorganised after localised and long continued applications of short warm and thick high frequency

sparks. These last should measure from 1 to 10 centimetres; the longest ones produce a deep, striking and penetrating action, which consequently is of great utility in visceral tumours. visceral tumours. This striking and penetrating action is deeper and more marked in bipolar sparks and effluves

The friability of the cancerous cell in the presence of high frequency "scintillation" is such that the neoplastic cell seems to vanish and disappear after a short time by a process of deliquescence, and this is the case, not only with regard to the spark, but even to the effluve.

Effluvation should be preferred when it is necessary to modify specially delicate parts, those which have been less deeply affected or only infiltrated. For this reason I give it the preference in certain cases for the modification of the wound caused by the surgeon's the modification of the wound caused by the surgeon's knife, when the operation itself had been considered radical.

High frequency "scintillation" is a powerful anæsthetic, as d'Arsonal has shown from the very first. The first shock, to speak the truth, takes the patient by surprise, and is painful only to a very small degree, but almost immediately he becomes accustomed to it and soon bears without any pain sparks of any dimension or thickness, even the thickest sprays, and remains perfectly quiet during the entire duration of the sitting.

Chloroform is absolutely useless for all superficial and accessible tumours; those situated in cavities necessitate special isolating and localising electrodes. Thus, Doumer's condensating electrode is very serviceable in certain cases, as it protects the surrounding parts, besides by modifying its construction it can be made to give scintillations of pretty various lengths.

Large tumours and visceral neoplasms necessitate the

knife, and at first general anæsthesia.

High frequency "scintillation" given in the form of sparks or effluves exercises considerable antiseptic action by reason that it generates a large quantity of ozone at the commencement of its action. The electric and thermic forces exercise also this beneficent When sparks have been employed, drainage of the wound becomes necessary in order to eliminate the necrosed cells.

Effluves employed on healthy cells, far from producing mortification, hasten, on the contrary, the process of cicatrisation, and, far from prejudicing union by first intention, they act in such a way as to materially assist the advent of this auspicious result. Union by first intention, however, should only be sought for in those cases in which the surgeon considers he has performed a complete and radical excision of the growth.

#### CONCLUSIONS.

(1) I was the first to draw attention to the elective specific action of high frequency sparks and effluves on malignant neoplasms at the Congress of Medical Electrology and Radiology (July 27th—August 1st,

(2) Since 1900 I have urged the necessity of completing surgical operations on large malignant tumours with high frequency "scintillation" applied to the surgical wound so as to disinfect and to drain the new regions contaminated by the knife, and by so doing to avoid recurrence. This method has since been called "Fulguration." Since then I have added that high frequency "scintillation" constitutes the only therapeutic method of dealing with inoperable growths.

(3) As I pointed out in my communication of 1900, the effect of high frequency "scintillation" under the form of sparks and effluves is to eliminate the neoplastic tissues and to stimulate the tropho-neurotic curative action of the underlying healthy layers. The work of repair is undoubtedly the one I have indicated (a selector of the underlying healthy layers). sclerogenous processus which fills up rapidly the deficiencies caused by loss of substance, and thus leads to an excellent cicatrix being left).

(4) High frequency "scintillation" is sufficient for

superficial epitheliomata which are accessible to the electrodes; the knife should only be brought into play for large tumours and for those which are very deeply seated.

(5) In superficial epitheliomata, short or long effluves and the smallest sparks are sufficient to destroy the pathological elements and to stimulate the healthy tissues during their work of repair; with reference to other cases of malignant growths, it may be necessary, according to circumstances, to have recourse to more or less lengthy sparks and effluves, and to electrodes of various forms, so as to be able to localise the scin-

(6) Fulguration of the operation wound can be done either with sparks or with effluves; the former are necessary to complete an operation which has been acknowledged by the surgeon to be incomplete; the latter I consider sufficient and even preferable in cases where the operation has been deemed complete and

(7) In all cases, the seat of the operation should be submitted from time to time to high frequency effluvation so as to prevent recurrence.

#### SOME RECENT RESEARCHES

ON THE

#### FUNCTION OF THE NON-AUDITORY EAR.

By R. H. WOODS, M.B., F.R.C.S.I., Surgeon for Throat, Nose and Ear to Sir Patrick Dun's Hospital, Dublin.

I must first express my indebtedness to the works of Crum Brown, Alexander, Barany, Neumann, and others for much of the subject-matter of the following paper.

In determining the function of the non-auditory part of the ear, we are met at the outset with the difficulty that it does not communicate with the cortex of the brain, as do our other sense-organs. To discover the function of the eye, we have only to close our lids, and its use for sight is at once apparent; similarly by stopping the ear its acoustic function is disclosed. stopping the ear its acoustic function is disclosed. Our information concerning the labyrinth must, therefore, be derived from its indirect effects on other parts of the body; in other words, by its reflex phenomena. The internal ear, or labyrinth, is, roughly speaking, composed of three parts. The cochlea, in which is contained the end-organ of hearing; the vestibule, in which lie the eacoustic and strictly and the semi-

which lie the sacculus and utriculus; and the semi-circular canals, in which lie the membranous canals of the same name.

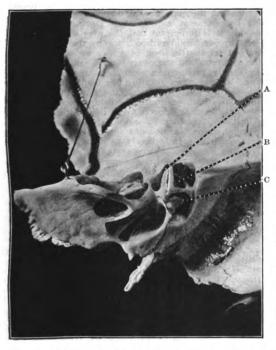

Fig. 1.-Dissected right temporal bone seen from above, behind and within.

A. Superior canal. B. External canal. C. Posterior canal.

There are three semi-circular canals, each occupying planes at right angles to the other two. Two are vertical, the anterior and posterior; the third lies horizontally. The two vertical canals make (as already mentioned) an angle of 90 with one another, and they are so placed that each makes an angle of 45° with the mesial plane. It will thus be seen that the plane of the anterior canal of one side is parallel with that of the posterior canal of the opposite side, while the horizontal canals are in the same plane.

Fig. 2.-Cast of left internal ear.

A. Ampulla of superior s.c. canal. B. Ampulla of horizontal canal. C. Ampulla of posterior canal.

Each canal is furnished at one end with a dilatation called an ampulla. The ampullæ of the superior and horizontal canals lie quite close together, and in immediate relation to the junction of the second and third stages of the facial nerve, by which they are separated from the fenestra ovalis. The ampulla of the posterior canal lies deeply at the lower end of the vestibule, where the lower end of the posterior canal enters it. The superior and posterior canals have a short portion common to both at the ends removed from their ampullæ.

In the bony labyrinth, and roughly corresponding to it, lies the membranous labyrinth. Contained in the bony semi-circular canals, and of similar shape, lie the much smaller membranous canals. These are attached by their convexities to the lining membrane of the bony canals, and all three open by both ends into one of a pair of membranous sacs which lie side by side in the vestibule. This sac is called the utriculus. The utriculus is connected by a fine duct with the other vestibular sac, the sacculus, and this is in turn connected with the membranous canal of the cochlea.

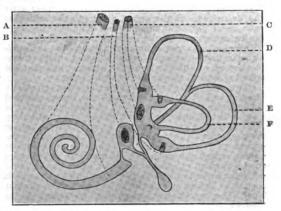

Fig. 3.-Diagram of the left membranous labyrinth.

A. Cochlear portion of VIIIth nerve. B. Portion distributed to the saccule and posterior ampulla.

C. Portion for the utricle and superior and horizontal D. Superior canal. E. Posterior canal. ampullæ. F. External canal.

Each membranous canal has a dilatation or ampulla corresponding with that of its bony canal. Each ampulla has a tiny crest, formerly called the crista acoustica, because its function was supposed to be an auditory one, but now named the crista ampullaris.

Each crista is supplied by filaments derived from the vestibular portion of the auditorv nerve, and from the cells of the crista delicate hair processes are joined together by some colloid material to form a small cap called the cupula. Each cupula projects a little beyond the middle of its ampulla.

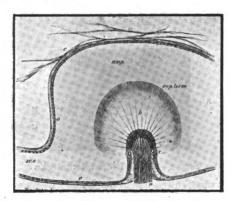

Fig. 4.—Semi-diagrammatic illustration of a membranous ampulla showing cupula (Schäfer).

On the walls of the sacculus and utriculus respectively are two patches of aggregations of cells, the maculus utriculi and the maculus sacculi. From these cells similar hair processes extend into a colloid material, in which are embedded crystals of calcium carbonate. One division of the estibular portion of the auditory nerve is distributed to the sacculus and the posterior ampulla, while the other goes to the utriculus and anterior and horizontal ampullæ. The central termination of the vestibular nerves is in the medulla in relation to Deiter's nucleus, from which filaments go upwards to the oculomotor nuclei and downwards to the anterior horns of the cord. The former are believed to be the path through which the eye reflexes travel, while through the latter are conveyed those impulses which influence equilibrium.

The first experimenter on the function of the semicircular canals was Flourens. He showed on pigeons that whenever any canal was destroyed, movements of the head, body, and eyes in the plane of that canal took place. This is called Flourens' law.

In order to explain the occurrence of movement after the destruction of the organ, Flourens assumed that each canal normally exercised an inhibitory influence on the movements of the body in its own plane.

Goltz, in 1870, put forward the theory that the semicircular canals were an organ to assist in the maintenance of equilibrium, and his opinion was that the stimulus worked through hydrostatic pressure.

Since that time, many investigators, but especially Breuer, and Mach, and Crum Brown, have explored this obscure region. As a result of their labours, it is now believed that the function of the vestibulary apparatus is to give a response to every change in our state as regards movement, whether in right lines, curves, or rotation. They hold that the semi-circular canals convey information with regard to any change in the angular velocity of rotation, while the function of the maculæ is similarly to convey information with regard to change in velocity of the body in a straight line. The mechanism, according to them, is as follows:—

The two maculæ are furnished with crystals of calcium carbonate, so-called statoliths, on the ends of their hair processes. When the head moves in any direction there is a tendency, owing to their inertia, for these statoliths to lag behind; this lagging is felt by the hair processes as a push or a pull according to the direction of the movement. And since the maculæ are situated at right angles to one another, any movement in the horizontal plane must have a corresponding reaction from one or both maculæ. It follows from this that, once movement in a straight line has become uniform, no information is conveyed as to the direction of that movement: the whole labyrinthine system must

be at rest with regard to itself, and hence no impression is carried. Everyone has tried the childish experiment of closing the eyes during a railway journey and imagining that the train is going in the opposite direction.

It is said that birds and fishes have three maculæ, the reason being that they move in three dimensions, while ordinary animals are confined to two. Whether this is the case or not, man is certainly not without a sense of his movement in the up and down direction, as anyone who has ever been in a lift or at sea can testify; but whether the information of that movement is conveyed by the labyrinthine apparatus may well be open to question; it may easily be furnished by increased or diminished pressure on the soles of the feet, and perhaps by variations in pressure of the contents of the stomach on its floor, at the beginning and end of the movement.

In the same way that the soles of the feet may convey information as to up and down movement, the skin on other parts of our body may help us in perceiving acceleration or retardation in right lines when we sit in a moving vehicle; but, even allowing for all this, there seems to be room enough left for the macula to be useful in connection with movements of various parts of the body with relation to one another, whether of the head to other parts, or of other parts to the head. Such a sense, to be useful, must be intimately bound up, as of course it is, with the muscular sense.

Their view of the semi-circular canal mechanism is as follows: When rotation begins, say, in the horizontal plane, the inertia of the endolymph causes it to lag behind. A relative current is set up in the horizontal canal in the opposite direction to the body movement. The effect of this current is to move the cupula of the crista ampullaris, and this movement constitutes the stimulus whereby we become aware that rotation has started, and whereby the important eye reflexes already referred to are liberated. An interesting and simple experiment in this connection may be made by closing one's evelids and gently laying the pulps of the fingers on them. If now we suddenly turn on our heel, the eyeballs may be felt to move or twitch from side to side horizontally under the fingers, the twitching being quicker in the direction of the body movement than in the opposite one. The reason for such a thing happening is easily seen. During rotation of the body it is important that the eyes should fix the objects in our neighbourhood, for by this fixation we learn our relation to them in a way we could not do if the eyes remained stationary in the head, and passing objects only produced a blurred impression on the retina. Hence, when rotating our bodies, say, to the right-i.e., in the direction of the hands of a clock lying on its back-the eyes lag behind looking at or fixing neighbouring objects until they get too far to the left for comfort. The eyes then make a quick movement in the direction of rotation, and fix a second point, which in turn is slowly followed back, and so on. Thus the eyes, during rotation of the body, undergo a series of quick movements in the direction of rotation, alternating with slow ones in the opposite direction. This is called nystagmus. Now, this nystagmus, which, on account of being quick in one direction and slow in another is called rhythmic. is, as we shall see, a pure labyrinthine reflex, and has for its exciting cause distortion of the cupula by the endolymph. It must be distinguished from that variety which is found as a congenital defect in Albinos, and as an acquired one in certain diseases of the eye, and consists of oscillations of equal rapidity in both This latter is therefore called undulatory directions.

Vestibular nystagmus is always increased by looking in the direction of the quick movement, and diminished by looking in the opposite direction, and this gives us a ready means of estimating its degree.

a ready means of estimating its degree.

It is said to be of the first degree when it is only evoked by looking in the direction of the quick movement. The second is where it exists while the patient looks straight forwards, and the third is where it is not suppressed when looking in the opposite direction. Mach and Breuer hold that the immediate cause of this rhythmic nystagmus, therefore, is distortion of

the cupula of the crista by the endolymph. Thus, in starting horizontal rotation to the right round a vertical axis, a current is set up in the right horizontal semi-circular canal, which tends to distort the cupula away from the canal, and towards the utricle, and the effect of this distortion is horizontal nystagmus to the right. Again, when rotation has been uniformly continued for some time, the endolymph partakes of the general movement of the labyrinth, the cupula reverts by its elasticity to its normal position, and the system is brought to internal rest. If now the rotation is stopped, movement of the endolymph is, by virtue of

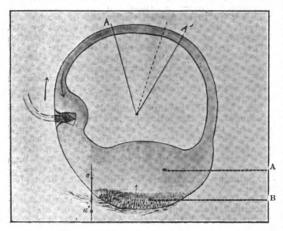

Fig. 5.—Diagram of semi-circular canal and utricle. A. Utricle. B. Masculus.

its inertia, once again started, the movement being in the direction of rotation—that is, relatively opposite to its first movement. The cupula is therefore distorted in the opposite direction (inclining in the right ear towards the canal), and nystagmus in the opposite direction takes place. Thus, during right rotation, nystagmus to the right takes place, and when rotation stops we get the "after" nystagmus in the opposite direction—viz., to the left. For convenience this after nystagmus is the only one observed, and it is used to measure the effect of rotation on the labyrinth, and therefore its irritability.

(To be concluded in our next.)

#### OPERATING THEATRES.

KING'S COLLEGE HOSPITAL.

GASTRO-ENTEROSTOMY.—MR. A. CARLESS operated on a middle-aged woman who had been for years the subject of gastric ulcer. The usual remedies and dieting had been more or less effective, but she was unable to take solid food, and every now and then her symptoms-sickness and pain-became urgent. There was some tenderness in the epigastrium on palpation, but the patient was a little indefinite as to whether the spot of maximum tenderness was in the middle line or a little to the right of it. There was some history of loss of blood by the bowel, but it was There was some doubtful as to whether it was a true melæna. Hæmatemesis had never occurred. On examination the patient's nutrition was fairly good; there was no evidence of gastric dilatation. It was obviously a case in which gastro-enterostomy might be expected to be beneficial. The operation was conducted in the usual way through a median incision externally just below the umbilicus. The stomach was examined, and some evidence of kinking found in the neighbourhood of the pylorus. On turning up the transverse colon and dividing the transverse meso-colon it was found that adhesions were present between the posterior wall of the stomach and the peritoneum covering the pancreas, and a little ingenuity was required to secure a suitable portion of the posterior gastric wall for establishing the anastomosis. The upper portion of the jejunum was then found, and clamped together with the stomach by Robson's clamps. Openings of one inch and three-quarters were made in each of these viscera, and the artificial communication established by two rows of sutures—front and back, silk being the material employed. A few of the larger vessels in the walls of the stomach were secured by passing a suture beneath them and tying. One or two stitches were also introduced between the jejunum and the stomach to the right of the anastomosis in order to maintain the direction of the jejunum and prevent kinking. The parts were subsequently replaced, and the abdomen closed in the usual way.

Mr. Carless pointed out that considerable importance must be attached to the direction in which the incision in the stomach is made; if it be made so that when the stomach is replaced the long axis of the communication is directed from below, upwards, and to the right, it is more likely that the jejunum below the communication will become kinked, and "vicious circle" vomiting of bile established. It is desirable, he said, that in gastro-enterpstomy the direction of the long axis should be from above, downwards, and to the right, so that the jejunum passing onwards has no sudden alteration in its direction.

PADDINGTON GREEN CHILDREN'S HOSPITAL. ARTHRECTOMY OF KNEE-JOINT. — MR. ARTHUR EDMUNDS operated on a girl, æt. 8, who had been under observation for three years. The disease manifested itself by wasting of the limb, thickening of the synovial membrane, and a certain varying amount of fluid in the joint. At no time did the patient have pain of any consequence. Complete rest, followed by ambulatory treatment with a Thomas's knee-splint, had been carried out during the whole time when under observation, the diagnosis being synovial tubercle of the knee-joint (a point which was confirmed by the operation). The child's surroundings were none too favourable for treatment, and there was reason to believe that medical orders were not carried out at home; at any rate, the condition did not ameliorate, and it was felt that it would be advisable to perform an operation. Operations on tuberculous joints, Mr. Edmunds said, although extremely satisfactory from the point of view of removal of disease, leave much to be desired as regards the functions of the joint and the growth of the limb, especially in young children. Fortunately, in these cases non-operative measures are very successful, and although a large number of these have been introduced, the essential points remain the same—namely, rest and fixation of the joint; and, with the increasing facilities provided by various philanthropic agencies for keeping children at the seaside for long periods, arthrectomies are becoming much less frequent operations. The degree to which recovery can take place is often very complete, a slight limitation of movement and muscular atrophy being the only indications of the disease which persist. Any surgical operation will almost certainly be followed by deformity of the joint, or, in the case of the knee, by considerable limitation of movement and shortening; it is for this reason that in the present case a prolonged trial was given to non-operative measures before attempting to remove the diseased portions.

A large U-shaped flap of skin was turned up in front of the knee-joint, its upper limbs extending to the upper limit of the synovial membrane (a tourniquet was applied before the incision was made); the patella was then sawn across, and the quadriceps extensor reflected until the limits of the synovial membrane were reached. The thickened pouch in front of the femur was dissected off the bone, and then the whole of the synovial membrane of the joint excised in one piece; the crucial ligaments were divided so as to gain access to the posterior part of the joint, but a few fibres of the lateral ligaments were saved, so as to give lateral stability to the joint. In one or two places there was superficial infection of cartilage, and here the affected portions were cut away. The wound was washed out thoroughly, the patella wired, and a drainage tube inserted to allow any blood to run away, and the wound closed.

The child had very little pain after the operation, and ten days afterwards everything was completely

healed with the exception of the opening for the drainage tube, which latter had been removed after 48 hours.

#### SPECIAL REPORTS.

#### GENERAL MEDICAL COUNCIL.

EIGHTY-NINTH SESSION.

FOURTH DAY.-FRIDAY, MAY 28TH, 1909.

The President, Sir DONALD MACALISTER, in the Chair.

THE minutes of the last meeting were taken as read and confirmed.

The following official intimation of the appointment

of a member of the General Council :-

We, the Council of the Victoria University of Manchester, in pursuance of the power given to us by the Medical Act (1886), do hereby appoint John Dixon Mann, M.D., F.R.C.P., to be a member of the General Council of Medical Education and Registration of the United Kingdom, for the term of two years from the 12th day of May, 1909.
F. FORBES ADAM, Chairman of Council.

ALFRED HOPKINSON, Vice-Chancellor.
(On behalf of the Council.)

The following were elected as members of the stated

Committees:

Examination Committee.—English Branch Council: Drs. Taylor, Saundby and Caton. Scottish Branch Council: Sir Thos. Fraser, Drs. Finlay and McVail. Irish Branch Council: Sir John Moore, Sir Chas. Ball, Dr. Kidd.

Education Committee .- English Branch Council:

Education Committee.—English Branch Council:
Dr. Norman Moore, Sir G. Philipson, Sir John
Williams. Scottish Branch Council: Dr. Mackay,
Mr. Hodsdon, Dr. Knox. Irish Branch Council:
Sir Thos. Myles, Sir C. Nixon, Dr. Little.
Public Health Committee.—English Branch Council:
Dr. Cocking, Mr. Power, Dr. McManus. Scottish
Branch Council: Dr. Norman Walker, Sir John
Tuke, Dr. McVail. Irish Branch Council: Sir John
Moore Dr. AdvecCurran Dr. Kidd Moore, Dr. Adye-Curran, Dr. Kidd.

Pharmacopaia Committee.—The President, Chairman; Drs. Norman Moore, Barrs, Little, Caton and McVail, Sir John Moore, Sir G. Philipson, Sir Thos.

Fraser.

Finance Committee.—Mr. Tomes, Chairman; Mr. Morris, Sir John Tuke, Dr. Little.

Dental Committee.—The President, Chairman; Mr.

Morris, Mr. Tomes, Mr. Hodsdon, Sir Thos. Myles. Denial Education and Examination Committee.— Mr. Tomes, Chairman; Mr. Morris, Drs. Knox and Finlay, Sir Thos. Myles, Sir Chas. Ball.

riniay, Sir Thos. Myles, Sir Chas. Ball.

Students' Registration Committee.—Sir Hugh
Beevor, Chairman; Drs. Norman Moore, Mackay, and
Adye-Curran, Sir J. Batty Tuke, Sir Ch. Nixon.

Moved by Sir Hugh Beevor, seconded by Dr.
LITTLE, and agreed to:—"That Mr. H. Stansfield
Collier, F.R.C.S.Eng., be appointed Assistant
Examiner in Surgery to the Apothecaries Society of
London, vice Mr. McAdam Eccles, who retires by
rotation."

Moved by Dr. Norman Moore, seconded by Sir John Moore, and agreed to:—"That the report from the Pharmacopæia Committee be received and entered

in the minutes."

Moved by Sir Hugh Beevor, seconded by Dr. Norman Moore, and agreed to:—"That the report from the Students' Registration Committee be received,

entered in the minutes, and approved."

On motion from the Chair it was resolved:—"That the report from the Finance Committee be received and entered in the minutes."

Moved by Dr. McVall, seconded by Dr. Caton, and agreed to:—"That the report from the Examination ommittee on the returns as to examinations for the

Moved by Dr. McVail, seconded by Sir Christopher Nixon, and agreed to:—"That the table showing results of a competition held in May, 1909, for com-

missions in the Royal Navy be received and entered in the minutes.'

Moved by Dr. McVail, seconded by Sir Christopher Nixon, and agreed to:—"That the thanks of the Council be conveyed to the Director-General of the Navy Medical Service for the returns which he has again furnished to the Council, with the request that these returns may in the future continue to be furnished to the General Medical Council."

Moved by Sir John Moore, seconded by Dr. Norman Moore, "That the report from the Public Health Committee be received, entered in the minutes, and approved." After a discussion with reference to reducing by three months the period of compulsory study for the M.O.H., an amendment moved by Mr. Thomson, seconded by Sir Christopher Nixon, "That the report be referred back to the Public Health Committee for re-consideration," was lost; the original motion was then put and carried.

Strangers then withdrew in order that the Council might receive in camerá, a report by the Executive

Committee.

The Council having resumed, announced that the following had been elected memannounced that the following had been elected members of the Executive Committee:—Dr. Norman Moore, Sir Hugh Beevor, Mr. Tomes, Dr. Langley Browne, Sir John Tuke, Dr. McVail, Sir John Moore, Sir Charles Ball; and that the following had been elected members of the Penal Cases Committee:—Dr. Saundby, Mr. Tomes, Dr. Finlay, Sir Christopher Nixon.

Council then resumed the consideration adjourned from November 27th, 1908, of the facts proved against William John Watson. On May 24th, 1909, the Dental Committee had drawn up a supplementary report which ended by stating that "the committee cannot regard the evidence presented by W. J. Watson as to his conduct in the interval as satisfactory."

Mr. Watson attended in answer to his notice. He

was not accompanied by counsel or solicitor. The British Dental Association, the complainants, were represented by Mr. R. W. Turner, their counsel, instructed by Messrs. Bowman and Curtis-Hayward, solicitors.

The Registrar having read the report, leave was accorded to Mr. Watson to address the Council, which

Mr. Turner having also spoken, the Council deliberated on the case in camera. Strangers having been re-admitted, the President announced the judgment of the Council as follows:—Mr. Watson, the Council has again given careful consideration to the two reports of the Dental Committee, and has deferred the further consideration of your case to November next, when you will be required to be present in person and to produce satisfactory evidence, and not merely a personal statement, as to your professional good conduct in the interval, with particular reference to your undertaking to discontinue all advertising, or connection, direct or indirect, with those who are advertising.

The Council resumed the consideration adjourned from November 27th, 1908, of the facts proved against Charles Morgan in regard to whom the Dental Committee, at its meeting on Monday, May 24th, 1900, drew up a supplementary report, stating inter alia that C. Morgan still continued to advertise on the curtain of the Empire Theatre, Newport.

Mr. Morgan attended in answer to his notice, accompanied by Mr. Arthur P. Poley, his counsel, instructed by Mr. H. Morgan Rees, solicitor, of

The complainants, the British Dental Association, were represented by R. W. Turner, counsel, instructed by Messrs. Bowman and Curtis-Hayward, solicitors.

The Registrar having read the report, Mr. Poley sought and obtained leave to address the Council on the report. He read a letter from the Secretary of the London and Provincial Advertising Agency, Limited, consenting to withdraw the advertisement from the curtain at the Empire Theatre, Newport, on certain terms, and asked that the Council would post-pone judgment in order that Mr. Morgan might have an opportunity to show that this had been done.

Mr. Turner did not desire to offer any observations

The Council deliberated on the case in camerá, and strangers having been re-admitted, the President announced the judgment of the Council to be as

Mr. Morgan: The Council has again given careful consideration to the reports of the Dental Committee, and has deferred the further consideration of your case to November next, when you will be required to be present and to offer satisfactory evidence other than your own statement as to your prcfessional good conduct in the interval, with particular reference to your promise to discontinue the issue, direct or indirect, of all advertisements.

The Council resumed the consideration of the report of the Dental Committee on the charge against Samuel David Davis, of Wisbech, Cambs., of acting as dentist and general assistant to a Dental Company at Wisbech, none of the directors or shareholders of which are registered dentists, and unregistered persons, being in its employ.

The Registrar having read the report, Mr. Davis sought and obtained leave to address the Council on

the report, which he did.

Mr. Turner did not desire to address the Council in reply on the part of the British Dental Association. Strangers having been re-admitted, after the Council had deliberated in camera, the President announced the decision of the Council as follows:—

Mr. Davis, I have to inform you that the Council has given careful consideration to the report of the Dental Committee, and that they have judged you to have been guilty of infamous and disgraceful conduct in a professional respect, and have directed the Registrar to erase from the Dentists' Register the name of Samuel David Davis.

The Council proceeded to the consideration of the report of the Dental Committee on the charge against Frederick Joseph Whitehead, of Wisbech, Cambs.

The complaint was the same as against S. D. Davis, and had reference to the same company and the same unregistered persons.

Mr. Whitehead did not attend, nor was he repre-

The complainants, the British Dental Association, were represented by Mr. R. W. Turner, counsel, instructed by Messrs. Bowman and Curtis-Hayward, solicitors.

The Registrar having read the report, Mr. Turner, on question from the Chair, intimated that he did not desire to address the Council.

The Council then deliberated on the case in camera. Strangers having been re-admitted, the President announced the judgment of the Council as follows:—
Mr. Turner: I have to announce that the Council

have given careful consideration to the report of the Dental Committee, and have judged Mr. Frederick Joseph Whitehead to have been guilty of infamous and disgraceful conduct in a professional respect, and have directed the Registrar to erase from the Dentists' Register the name of Frederick Joseph Whitehead.

The Council proceeded to the consideration of the report of the Dental Committee on the charge against Reuben Davis, whose present address was Boston, U.S.A., and who had been convicted in England on three separate occasions of larceny.

Mr. Reuben Davis did not attend in answer to his

notice, nor was he represented by counsel or solicitor.

The Registrar read the report of the Dental Committee, and after the Council had deliberated in camerá, and strangers having been re-admitted the President announced the judgment of the Council as follows :-

I have to announce that, it having been proved that Reuben Davis has been convicted of various misdemeanours as set forth in the report of the Dental Committee, the Registrar has been directed to erase from the Dentists' Register the name of Reuben Davis.

The Council proceeded to the consideration of the report of the Dental Committee on the charge against Stanley Bennett Wakefield, who had been convicted at the Marlborough Street Police Court of illegal pawning, and who had also made a false and fraudulent claim.

Mr. Wakefield did not attend in answer to his

notice, nor was he represented by counsel or solicitor.
The complainants, the British Dental Association, were represented by Mr. R. W. Turner, counsel, instructed by Messrs. Bowman and Curtis Hayward, solicitors.

The Registrar having read the report, Mr. Turner, in answer to a question from the Chair, stated that he did not desire to address the Council on the report.

Strangers having been re-admitted after the Council had deliberated in camera, the President announced the decision of the Council as follows:—

I have to announce that, it having been proved that Stanley Bennett Wakefield has been convicted of a misdemeanour, the Registrar has been directed to erase from the Dentists' Register the name of Stanley Bennett Wakefield.

The Council proceeded to the consideration of the report of the Dental Committee on the case of Thomas Parkins, of Salford, Manchester, who had allowed part of his practice as a dentist to be carried on at Sharrow Head House, Sheffield, by his son, Charles Henry Parkins, an unregistered person.

The Registrar having read the report, Mr. Parkins addressed the Council, and Mr. Turner replied for

the British Dental Association.

Strangers having been re-admitted after the Council had deliberated in camera, the President announced the decision of the Council as follows:

Mr. Parkins: I have to inform you that, upon the facts found in the report of the Dental Committee, the Council have judged you to have been guilty of infamous or disgraceful conduct in a professional respect, and have directed the Registrar to erase from the Dentists' Register the name of Thomas Parkins.

Strangers by direction from the Chair again with-drew, in order that the Council might consider a

matter in camera.

On strangers being re-admitted, the Council proceeded to the consideration of the case of Thomas Torrens McKendry, registered as of 30 Wellwood Road, Goodmayes, Ilford, Essex, M.B., Bac. Surg., 1894, R. Univ. Irel., who has been summoned to appear before the Council on the following charge a: formulated by the Council's solicitor:-

"That you have knowingly and wilfully on various occasions, and in particular on the 20th day of February, 1909, assisted one E. C. Dalby, a person not registered as a dentist, in carrying on practice as a dentist by administering anæsthetics on his behalf to persons coming to him for treatment, and that in relation thereto you have been guilty of infamous conduct in a professional respect."

The complainant was Mr. Victor Albert Chatelain.

Mr. McKendry attended in answer to his notice. He was not accompanied by counsel or solicitor. Mr. Chatelain, the complainant, attended in person, without counsel or solicitor.

The Council's solicitor having read the notice, Chatelain proceeded to open his case. He called Mrs. Florence Jane Chatelain as a witness, and examined. the Mr. McKendry did not desire to cross-examine the witness. He called Mr. William Raymond Bryan as a witness, and examined him. Mr. McKendry did not desire to cross-examine the witness, who answered questions put to him by the Legal Assessor. Mr. Chatelain read a declaration by Mr. Richard Henry Stevens, L.D.S., R.C.S., Eng., a registered dentist of Ilford, which he put in. He next called Mr. Joseph Bethel Cox, a registered medical practitioner, of Seven Kings, as a witness and examined him. He was cross-examined by Mr. McKendry, and answered questions put to him by the Legal Assessor.

Mr. Chatelain then made a statement by way of evidence, and was cross-examined by Mr. McKendry.

Mr. McKendry then addressed the Council on his own behalf, and tendered his statement as part of the evidence for the defence. He was cross-examined by Mr. Chatelain. Mr. McKendry also answered questions put to him by the Legal Assessor.

Mr. McKendry called Mr. Henry Charles Dalby as

a witness, and examined him. He was cross-examined by Mr. Chatelain, and re-examined by Mr. McKendry.

He also answered questions put to him by the Legal

[Moved by Dr. NORMAN MOORE, seconded by Dr. LITTLE, and agreed to :—" That the Council meet at ir o'clock a.m. to morrow in order to deal with the remaining items on the programme of business.

Mr. Chatelain then addressed the Council in reply. Strangers and Mr. McKendry having been re-admitted after the Council had deliberated in camera, the President announced that the Council had found that the facts alieged in the notice of inquiry had been proved to the satisfaction of the Council.

Mr. McKendry gave his assurance that he would not again transgress against the resolution of the for unregistered dentists, and expressed his regret that he had done so on several occasions.

Strengers then withdrew in order that the Council might consider its judgment. Strangers having been re-admitted, the President announced the decision of the Council as follows:—

Mr. McKendry: The Council has postponed judgment till the November session, when you will be required to attend in person and to produce evidence, more particularly from medical colleagues in your neighbourhood, as to your professional good conduct generally in the interval, and in particular that you have not repeated the offence of which complaint has been made.

The Council proceeded to the consideration of the case of Robert Galbraith Reid, registered as of 202, Ewell Road, Surbiton, formerly of 176 Lambeth Road, S.E., M.B., Mast. Surg., 1887, Univ. Glasg., who had been summoned to appear before the (ouncil on the following charge as formulated by the Council's solicitor :-

That you abused your position as a medical man by having sexual intercourse with one Annie Wahl when you were in her house at 31, Stangate Street, Lambeth Road, S.E., as a medical man professionally attending her husband, Joseph Wahl, and by sub-sequently attempting to have sexual intercourse with her, and that in relation thereto you have been guilty of infamous conduct in a professional respect."

The complainant was Mrs. Annie Wahl

Mr. Reid attended in answer to his notice, accompanied by Mr. Forrest Fulton, his counsel, instructed by Mr. Arthur Giles, his solicitor.

Mrs. Wahl attended in support of her complaint, accompanied by Mr. Vaughan Whitehead, her solicitor.

Mr. Whitehead opened the case for Mrs. Wahl, and called her as a witness, and commenced his examination-in-chief.

Six o'clock having arrived, the Council adjourned.

#### FIFTH DAY.-SATURDAY, MAY 29TH, 1909.

The President, Sir DONALD MACALISTER, in the Chair,

THE whole of the day was taken up by the consideration, adjourned from Friday, May 28th, of the case of Robert Galbraith Reid, M.B., M.S., Univ. Glasgow.

Mr. Whitehead continued his examination-in-chief of Mrs. Wahl, the complainant. She was then severely cross-examined by Mr. Forrest Fulton, and questions put to her by the Legal Assessor.

Mrs. Elizabeth Bailey, Mrs. Wahl's mother, was next examined by Mr. Whitehead, and cross examined by Mr. Forrest Fulton.

Mr. Wahl, husband to Mrs. Wahl, was then

examined by Mr. Whitehead, cross-examined at some length by Mr. Forrest Fulton, and re-examined by Mr. Whitehead. He also answered questions put to him by the Legal Assessor.

Mrs. Annie Westen was examined by Mr. Whitehead, cross-examined by Mr. Forcest Fulton, and re-

examined by Mr. Whitehead.

At six o'clock the President announced that a Committee had been formed to consider the subject of Annesthetics, and to report on this question to the Council at the November session.

The Committee consisted of:—The President, Mr.

Morris, Mr. Tomes, Mr. Hodsdon, Sir Charles Ball, Dr. Knox.

The Council then adjourned.

#### SIXTH DAY .- TUESDAY, JUNE 1ST, 1909.

#### The President, SIR DONALD MACALISTER, in the Chair,

On strangers being re-admitted after the Council had considered certain matters in camera, the minutes of the last meeting were taken as read, and confirmed. The Council resumed the consideration, adjourned from Saturday, May 29th, 1909, of the case of Robert G. Reid, M.B., M.S., Univ. Glasgow.

The President informed the parties that the Council had decided to sit that day, with the usual intervals, so long as might be necessary to finish the hearing of

Mr. Whitehead called Isabella Mitchell and by examined her. The witness was cross-examined by Mr. Forrest Fulton, re-examined by Mr. Whitehead, and answered questions put by the Legal Assessor. Mr. Whitehead's other witnesses not having arrived, the ordinary business of the Council was proceeded with.

Moved by Dr. NORMAN MOORE, seconded by Mr. THOMSON, and agreed to:—"That the report from the Dental Education and Examination Committee be received and entered on the minutes." The report had reference to a letter received from an educational body, the Incorporated Dental Hospital of Ireland, calling attention to a certain difference existing between the requirements of the several bodies granting licences in dental surgery-viz., with regard to the year or years of bond fide apprenticeship with a registered dental practitioner.

Moved by Mr. Morris, seconded by Sir Chas. Ball.

and agreed to:—"That the Report of the Denta!
Education and Examination Committee be communicated to the R.C.S.Eng. for such observations as that body may be inclined to offer. The case of R. G. body may be inclined to offer. The case of R. G. Reid was then proceeded with.

Mrs. Amelia Nicholls was examined by Mr. White-

head and cross-examined by Mr. Forrest Fulton.
W. Nicholls and Ernest Wahl were examined, cross-

examined, and re-examined, and answered questions put by the Legal Assessor.

Mr. Forrest Fulton then addressed the Council in defence of Mr. Reid. During his speech he traversed the evidence given against his client, and said that

if it were believed no doctor would be safe. He then called Mr. Reid and examined him. his examination-in-chief, he obtained permission from the Council to call Dr. Hector Mackenzie, who had been waiting for a long time, and examined him as to Mr. Reid's character Dr. Mackenzie was cross-examined by Mr. Whitehead.

Mr. Reid was then cross-examined by Mr. White-

head, and answered questions put to him by the Legal Assessor.

Mrs. Isabel Sophia Reid was next examined by Mr. Forrest Fulton, and answered questions put by the Legal Assessor.

As witnesses as to character Mr. Forrest Fulton called the Rev. Mr. Shepherd, Rector of Great Parnham, Essex, and formerly of Lambeth; the Rev. Mr. Hayes, Vicar of Holy Trinity, Lambeth; the Rev. Mr. Payne, Vicar of St. Andrews, Old Kent Road: Dr. Charles Sangster, of Lambeth; Mr. Honey, solicitor; Dr. S. M. Dowling, of Lambeth Road; Mrs. Lucy Langheimer, a nurse; Mrs. Wright and Miss Pearson, who had been employed as dispenser by Mr. Reid for two years

He also called Mr. Giles, solicitor, and examined im. The witness was cross-examined by Mr. White-

Mr. Whitehead then briefly addressed the Council. On strangers being re-admitted after the Council had deliberated in camera, the President addressed Mr. Reid as follows: The Council have come to the following resolution:—"That the facts alleged against you in the notice of inquiry have not been proved to the satisfaction of the Council."

Moved by Dr. NORMAN MOORE, and seconded by Dr. MACKAY:—"That the Report from the Education Committee on various proposals submitted to them referring to the curriculum in medicine be received and entered on the minutes."

An amendment, moved by Mr. Morris, and seconded by Mr. Thomson, "That the following words be added to the motion, 'and that it be circulated to the licensing bodies for their observations,'" was lost. The original motion was then put and carried.

Moved by Dr. Norway Mooney.

The original motion was then put and carried.

Moved by Dr. Norman Moore, seconded by Dr.

Finlay, and agreed to:—"That the consideration of
the Education Committee's Report be taken on the
first day of the November Session."

Moved by Dr. Norman Moore, seconded by Sir John
Moore, and agreed to unanimously. "That Mr. Allen

MOORE, and agreed to unanimously: "That Mr. Allen be appointed General Registrar of the Council till the

end of the summer session, 1910."

Moved by Dr. NORMAN MOORE, seconded by Mr. THOMSON, and carried by acclamation:—"That the best thanks of the Council be given to the President for his able services in the chair during the present session.

The Council then rose.

#### TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF ANATOMY AND PHYSIOLOGY.

MEETING HELD FRIDAY, APRIL 23RD, 1909.

The President, Dr. T. H. MILROY, in the Chair.

THE MECHANISM OF DEGLUTITION.

PROFESSOR W. H. THOMPSON made a communication on the above. He said the usual conception of the act of swallowing was that it consisted of three stages mouth, pharynx, and esophagus. But when one reflected it was obvious that the act was a reflex one, and, as such, would be discharged from certain places and by certain stimuli. It had been proved by ex-periment that the starting of the swallowing reflex was sufficient to carry the movement right down to the lower end of the esophagus, even though a segment of the esophagus were cut out, provided the nerves were retained intact. It is true, different conclusions on this point had been reached, but the divergences were explained by differences in the conditions of the experiments, such as depth of anæsthesia, etc. The same law had been shown to hold good in the human subject in a case of cervical esophagotomy, for when food was put in the lower segment of the esophagus it remained there until an act of swallowing was started from above, which travelled over the point of sever-ance and carried the bolus down. The areas from which the reflex could be discharged had also been investigated both in the lower animals and in man. The only thing necessary for the discharge was the contact of a properly prepared bolus with a definite spot of mucous membrane. After that the act was automatic. On further reflection it seemed rather unnatural to include in the act of swallowing anything prior to discharge of the reflex from the mechanical prior to discharge or the renex from the mechanical contact of the bolus with the defined area of mucous membrane. The act of swallowing would thus consist of two stages—(1) the stage immediately following the contact of the mucous membrane and the bolus, by which the latter was projected into the esophagus; and (2) the passage through the esophagus. Anything prior to these stages belonged to the preparation for swallowing, not strictly to the act itself. As regards the preparation, it was to be remembered that the pharynx, for the greater part of its time, was engaged in taking in air; it was only an occasional duty to perform the act of swallowing, and to safeguard the air passages from concomitant danger. The closure of the nose offered no difficulty; that of the larynx had also been satisfactorily explained, but the chief point of dispute present the plained; but the chief point of dispute concerned the part played by the epiglottis. It had been shown long ago that the epiglottis moves down in the act of swal-

lowing, but the investigations of Anderson Stuart somelowing, but the investigations of Anderson Stuart some sixteen to eighteen years ago pointed to a different conclusion. They were opposed at the time by Kanthack and Anderson, but the point remained unsettled. Recently a Dutch investigator, Eykman, had studied the movements of the epiglottis by Röntgen rays, and had shown that it did descend in swallowing, the free movements are the point of the bolus and carrying margin sweeping down behind the bolus and carrying on any fragments left behind. With regard to the propelling force, it had been stated by Kronecker and Metzer that the contraction of the mylohyoid muscles gave a starting thrust which was sufficient to shoot the bolus through the whole esophagus.

Professor Thompson showed the tracings on which the conclusions had been based, and considered that the conclusions had been based, and considered that they had been misinterpreted. It appeared to him that the proper explanation was that, on the moment of the discharge of the swallowing reflex, there was the discharge of the swallowing renex, there was started not merely a wave of contraction, but also a preceding phase of inhibition, to allow the easy passage of the bolus, and that this extended down into the esophagus for fully half its length. Such a condition of relaxation remained continuous in a series of acts of swallowing, as in the long esophagus of a horse, till the last act was discharged, when the larynx fell back and a wave of peristaltic contraction fol-lowed. A liquid bolus had not been traced farther than the region of the arch of the aorta in the human. subject. It was by no means shot down with the extreme rapidity originally supposed by Kronecker and. Metzer. With semi-solid and solid boluses, the mechanism was one of peristalsis practically the wholeway through. It seemed that the bolus often rested for a considerable period in the lower fourth of the peristaltic waves before an opening of the cardiac orifice of the stomach took place.

Professor Symington said it was difficult to realise.

that the tongue could move so extensively as to move the epiglottis in the manner described. In many animals the epiglottis normally extended upwards behind the soft palate. Certain animals had the upper opening of the larynx permanently fixed in the naso-pharynx, and the food must pass on one or other sides of it. In man there was no period in life in which they knew the epiglottis to project upwards. into the naso-pharynx.

Professor Dixon said it was not uncommon to find! space in the lower part of the esophagus containing food and liquor.

Dr. Johnston, Professor McWeeney, and the Presi-

dent also spoke, and Professor Thompson replied. CRITICAL SOLUTION POINT OF URINE.

Mr. W. R. GELSTON ATKINS gave a communication

on this subject.

Professor Thompson thought the method would work out of great value if it were reliable, as it was much-

more convenient than freezing.

The President said he wondered if the mean-arrived at would not vary very considerably under-experimental conditions. The great advantage of freezing was that it prevented alteration in the composition of the urine, while the molecular concentra-tion of urine altered during the process of warming.

Professor McWeeney said the method gave an tended scale and power to judge of very much smaller differences in molecular concentration, but until it had been tried under various conditions he did not think they could say much about it, as it depended on a number of factors which did not appear to have been fully investigated. EXHIBITS.

The President showed microscopic slides showing neuro-fibrillæ by Cajal's silver method.

Professor Dixon exhibited a drawing apparatus.

A SPECIAL meeting of the Council of the Charity A SPECIAL meeting of the Council of the Charity-organisation Society will be held on Monday, June-28th, at 4.30 p.m., at Denison House, Vauxhall Bridge-Road, S.W., when Miss Amy Hughes, of the Queen Victoria Jubilee Nurses' Institute, will read a paper on "Provident Nursing." Sir Alfred Lyall, G.C.I.E., K.C.B., will take the chair, and the Right Rev. the-Bishop of Islington will speak. NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

MEETING HELD (IN LEEDS) MAY 21ST, 1909.

The President, Dr. J. W. MARTIN (Sheffield) in the Chair.

DR. E. O. CROFT (Leeds) showed the left kidney from a fatal case of

PYELITIS IN PREGNANCY. The patient died in coma a few hours after a series of three fits. She was six months advanced in her second pregnancy years before, and the labour had been followed by convulsions. The kidney was hydronephrotic, and contained a large quantity of milk-like pus. The dilated and thickened ureter contained caseous material. The right kidney was normal in size, and on naked-eye section showed evidence of slight fatty degeneration; its capsule stripped easily.

Dr. CROFT also showed a

LARGE, SOLID, BROAD LIGAMENT TUMOUR OF UNUSUAL CHARACTER.

It had been enucleated from the broad ligament of a woman, æt. 47, without injuring the corresponding tube and ovary. It weighed 141 lb., and measured 10 to 12 in. in various diameters. On section it showed a central well-defined oval mass, 5 or 6 in. in diameter, of the consistence of a soft uterine fibroid, and of a light brick red colour. This was surrounded by a broad band of material of a myxomatous appearance. From this area a considerable amount of fluid exuded. The tumour was apparently an odematous fibroid which had undergone central "red degeneration" and myxomatous degeneration of the peripheral portion.

Dr. Carlton Oldfield (Leeds) showed a speci-

men of

CARCINOMA OF THE CERVIX

which had been removed by Wertheim's method. The patient was only thirty years of age. She was also suffering from syphilitic rupia and ecthyma. One enlarged lymphatic gland was found in the parametrium close to the cervix.

Mrs. Orford (Pontefract) showed a specimen of

one-eyed monster (cyclo-cephalus).

Dr. J. B. Hellier read the notes of a case of DOUBLE UTERUS AND VAGINA, WITH UNILATERAL

HEMATOCOLPOS.

The patient, æt. 16, had menstruated regularly and normally for two years, with a little dysmenorrhæa.

For some months she had noticed a swelling at the ror some months see had noticed a swelling at the vulva, but only at the monthly periods. Retention of urine led her to seek advice. There was a normal vaginal passage leading to a normal cervix uteri on the left side. On the right was a cystic swelling occupying the whole length of the vaginal wall, and protruding from the vulva. On incising this about six ounces of dark red inspissated menstrual fluid but there was no sign of a hæmatosalpinx. The vaginal septum was completely excised. The patient has menstruated normally since.

Dr. HELLIER also showed a

UTERUS WITH DOUBLE PYOSALPINX.

The uterine body had been amputated because both thes and ovaries had to be removed. There was a tubes and ovaries had to be removed. septum extending to the os externum and completely dividing the uterus into two cavities.

#### EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD JUNE 2ND, 1909.

The President, Dr. JAMES RITCHIE, in the Chair.

A DISCUSSION on

EYE-STRAIN

was opened by Mr. GEORGE BERRY, who prefaced his remarks by saying that specialists, who were consultants, lacked the advantage of the general practitioner of being able to follow out the results of treatment, for in most cases they saw the patient only once or twice.

In the discussion which followed Mr. Berry's paper Dr. George Mackay expressed the opinion that part of the discomfort associated with astigmatism was due to ciliary action as well as to lid-pressure. While he did not as a rule use cycloplegics, he hought that they were cccasionally valuable in assisting at a complete study of the refractive error in difficult cases.

Dr. LYNE discussed the relation of ocular defect to migraine, and described some of the symptoms attributed to muscular imbalance. He agreed with Mr.

berry that the effects of slight divergence or convergence had been greatly overrated.

Dr. Sinclair pointed out that in many cases the symptoms of discomfort and headache produced by pypermetropia, etc., were temporary; if a patient were run down in health and suffered from these he might be relieved by wearing glasses, and as his health im-proved the glasses could again be dispensed with.

Dr. Main related some experiences in China, showing that among the Chinese prolonged exposure to the intense glare of the western sun was borne without any discomfert.

Dr. LUNDIE dwelt on the greater discomfort pro-

duced by the lesser degrees of error.

Dr. Thyne said that in his experience it was quite impossible to recognise any particular type of head-ache as specially associated with refractive error. He considered that in a case of headache if one failed to find any definite cause for it, the patient should at

once have the eyes properly examined.

In his reply, Dr. Berry said that the difficulty always was to foretell whether a given case would be improved by glasses, because one found that some individuals bore with no discomfort a considerable degree of refractive error, while others, with much less were greatly distressed by it. The nervous element had always to be taken into consideration.

Dr. ALEXANDER GOODALL read a paper on "A Pharmacological Study of the Value of Commercial Samples of Liquid Extract of Ergot, with notes on Ergot Standardisation." He pointed out that the present uncertainty regarding the chemistry of ergot renders standardisation necessary, and described the various methods in use. A number of tracings of the effects of various preparations on the blocd pressure and the uterus were demonstrated by means of the lantern.

#### CORRESPONDENCE.

#### FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, June 6th, 1909.

THE CAUSES OF DEPOPULATION IN FRANCE. CONTINUING his study of the causes of the depopulation in France, Prof. Courmont places, in the first rank, infantile mortality—that is to say, of children under one year old.

Theoretically speaking, there is no reason why a

child at that age, except under rare circumstances, should die. If it is of good constitution, as is generally the case, it can only succumb from some fault or imprudence on the part of the parents or those entrusted with its care. Possessing brand new organs, it can only die from some avoidable malady.

The mortality among infants in France is 15 per cent., representing a total of 120,000 infants per year. The mortality in England is 12 per cent., and in Norway and Sweden 8 per cent.

The principal maladies to which infants succumb in France are enteritis and affections of the respiratory tract. Six out of every ten deaths take place within

ten days after birth. The causes of the mortality might be traced to two principal origins: the quality of the milk and the care-

less treatment of children.

In nine cases out of ten the milk is responsible for infantile diarrhoea, and more especially where the child is bottle fed-contaminated milk, dirty bottles, dirty

For a child to be kept healthy it should be kept clean, and guarded against cold and contagious maladies (measles, scarlatina, diphtheria). The mother alone can assume the care of the children, and any derogation from these natural principles is due to neglect or imprudence.

The habit of placing children out at nurse, so general in France, is a great factor in infantile mortality. A child under one year cannot travel without serious risk, and it may be said that 50 per cent. of the children thus placed out do not attain their first

year.

As to the remedies against this useless infantile mortality, Prof. Courmont recommends the encourage-

ment of maternal nursing.

The well-to-do will not nurse, and the poor cannot. The former refuse the sacrifice from selfish motives, but the working classes cannot afford it, and for these the State should promote obligatory insurance, as is practised in Germany.

The production and sale of milk should be carefully controlled, and puericulture taught in the schools.

MORTALITY FROM TUBERCULOSIS.

Tuberculosis is the greatest plague of humanity, and yet it is one of the easiest to avoid. Any hope of stamping out the disease entirely is naturally absurd, but it is possible to reduce it by 50 per cent. at least.

In France about 150,000 deaths are due annually to that malady, and it might be affirmed that each year there are one million persons in France in whom tuberculosis is in a state of evolution, and yet what has been done against this decimating disease? Nothing.

During the course of the last century there were many great wars, and the shores were visited by cholera, and these calamities caused 21 million deaths. During the same period tuberculosis carried off from 10 to 15 millions.

The mortality per 10,000 inhabitants of large towns was calculated for 1905 as follows:—

31.80. ••• France ... ž6.99. Ireland ... ... ... ... Scotland ... ... 20.53. ... ... Germany ... 17.93. ... ... ... Italy ... England ... ... 16.94. ••• .. ... 16.30.

Thus the deaths from tuberculosis are double those

of England, Italy and Germany.

In order to understand the ætiology of tuberculosis, the seed and the soil should be considered. The seed can have both a human and an animal origin. The former comes almost exclusively from the expectora-tion, while the latter is, above all, bovine. Bovine tuberculosis is very general in France; in certain regions a quarter or a third of the animals are

The malady may be propagated through the meat, but the milk of tuberculous cows is the great efficient

Cause.

The Soil.—Man enjoys a certain immunity against

Broad where it has succeeded in the bacilli of Koch. Even where it has succeeded in penetrating the organism it is frequently encysted and No malady is more curable than tuberdestroyed. culosis, otherwise man would have long ago disap-

peared, decimated by the disease.

A healthy man, without hereditary taint, well nourished, well housed, ought to escape the disease; but numerous are the causes which weaken this relative immunity: heredity (predisposition), pregnancy, nursing, privations of all kinds, certain maladies (grippe), alcoholism, insalubrious dwellings, age (frequent under five years of age), and between 16 and 40, infrequent between 5 and 16. Tuberculosis is rare after 40 except in hard drinkers and persons suffering

from diabetes.

Until these last years the lungs were considered the natural entrance of the infection; the dust, penetrating with the inspired air, created primary tuberculosis of the lung. Prof. Courmont believes this idea to be erroneous, as the dust encounters great difficulty in entering the lungs, and when it overcobstacles, the lung defends itself efficiently. it overcomes all

For him, pulmonary tuberculosis is almost always secondary to infection of the ganglions, especially in

the chronic form. How do the ganglions become affected? Years ago Chauveau proved the facility with which the bacilli penetrate the digestive tract. According to Calmette, pulmonary tuberculosis is due to the ingestion of the bacilli of Koch (dust, milk, etc.).

Leseur and Courmont are of opinion that penetration is frequently effected in the child by the buccal mucous membrane, by sores on the head, by small cutaneous wounds, and the microbes go straight to the ganglions. In the dwelling of a tuberculous patient the child is frequently contaminated in this way; the flies carry the bacilli from the expectoration of the patient to the open sores of the child; tracheobronchic adenopathy is the consequence; later, consumption will follow.

ALOPECIA.

Doctors are frequently consulted for affections of the scalp, and more particularly for falling of the hair. The treatment of such cases requires to be well understood, for the success of the remedies used often depends on the manner in which they are applied. Before prescribing any treatment, says Prof. Brocq, it is necessary to elucidate one point often overlooked, and that is whether the scalp be dry or greasy.

A simple experiment suffices to remove any doubt. The patient is ordered to wash the head with soap and water, and after two or three days a piece of tissue paper is applied to the skin. If the scalp is dry, the paper is not stained; otherwise a greasy spot

is found at the point of contact.

Washing the head with soap and water is very useful in cases of seborrhoea; panama soap might be used or bran water in which the yellow of two or three eggs are beaten up in a pint of the liquid. This preparation is excellent for cleansing children's heads.

There is one agent much used at present which can render great service in certain cases—ether of petroleum. But great precautions must be taken in using it as it is so inflammable that it can take fire at a distance of two or three yards from a flame.

Consequently the patients should be warned never to use this preparation in a room with fire or light.

In intense seborrhea producing almost complete baldness, ether of petroleum is particularly useful. By alternating the ether frictions with a strong solution of formol, it is possible to provoke the growth of a fine down or even of adult hair after three or four months of the treatment.

If the scalp is dry, ether of petroleum should not be used as it may irritate the skin. Stimulant lotions such as the following might be prescribed:-

Tincture of jaborandi or cantharides, 1 oz. Soap liniment, 5 oz.

Hydrochl. of quinine, 15 gr. Hydrochl. of pilocarpine, 5 gr. Rum, 6 dr. Water, 4 oz.

In case of fair hair, proof spirit should take the place of rum, which might darken the colour.

Pityriasis of the scalp is best treated by one or

other of the following preparations:—
Lotions with liquid polysulphide of potassium, 30 to 100 drops for a quarter of a glass of hot water. The treatment should begin with 10 drops, and gradually increase until the limit of tolerance of the scalp is reached.

Two tablespoonsful of medicated coal tar to a glass of water meet the same end.

Liquid ammonia, 1 to 2 dr.

Rum, 4 dr.
Water, 4 oz.
To be applied with a soft tooth brush.

If the scalp is too dry, sulphur ointment might be used from time to time.

Precipitated sulphur, 2 dr. Cacao butter, 2 dr.

Castor oil, 2 oz. Peru balsam, r dr.

The ointment is applied at night and removed in the morning with soap and hot water, after which the extremities of the hair are gently rubbed with sweet

#### GERMANY. Berlin, June 6th, 1929.

A PAPER by Prof. A. Forel, quoted in the Deutsche Med. Zeitung, 34/09, deals with the TREATMENT OF EPILEPSY.

He says that all methods of treatment that have been lauded, with the exception of those by the bromine salts and abstinence from alcohol, have been lamentable failures. Wetterstrand claimed to have cured epileptics by suggestion; the writer is of opinion that the cases were really hysteria. The action of the bromine salts in epilepsy has long been known, but in general it has been so much misunderstood and used so wrongly by physicians, that it has fallen completely into discredit. Nearly all the epileptics that have consulted the writer have been wrongly treated. In the first place, experience has taught him that Charcot was right in recommending the three bromine salts, potash, sodium and ammonium in equal parts. But Toulouse had discovered the chief thing, viz., the substitution of the chloride of sodium in the system by the bromine salts, in order to obtain their effect. Formerly 6 to 10, and even 15 grammes had to be given to the adult, before the attacks ceased. If the chloride of sodium was kept back as much as possible very pronounced results were obtained with from 2 to 4 grammes pro die.

But practice has also taught us a number of other details. Above all, it has long been known that we must give the bromides in a very much diluted state, in order to avoid disturbances of digestion. Further, the bromides must not be given after mealtimes, as unfortunate chemical combinations are formed thereby; they must be given when the stomach is absolutely empty, half to three-quarters of an hour before food, so that they may enter the blood current in a highly diluted condition. In this way they are the most effective and cause the least disturbance. Further, we have to navigate between two rocks, between epilepsy on the one side and brominism on the other. The latter makes itself known chiefly by the acne and somnolence; such cases are to be watched carefully.

The bromide treatment frequently fails through want of perseverance on the part of both patient and physician. People are unnecessarily afraid of a bromide acne; or they imagine that they have done wonders when they have given 2 grammes of bromides for two or three months together without cutting off the salt at the same time. In reality they have done nothing at all. The attacks, that have been scarcely diminished, return worse than ever. The bromide treatment of epilepsy must be continued for years, and at least two years after the last attack has appeared

years after the last attack has appeared.

Finally, masked epilepsy and psychical epilepsy must not be confounded with ordinary epilepsy. In the two former, and especially in psychical epilepsy, the bromine salts have no effect, or, as frequently happens, a bad one; and in this form the writer has almost given it up. In masked epilepsy he has given them for some time, and occasionally has seen a good effect. For psychical epilepsy he knows no other form of treatment than the lunatic asylum, for the masked form abstinence from alcohol, life in the open air, bodily labour, and school discipline.

bodily labour, and school discipline.

In the borderland between epilepsy and grave hysteria, hypnotism and psychic analysis is to be recommended, they are the sovereign remedy for hysteria, but absolutely useless in epilepsy.

Since 1902 the writer has given bromides with exclusion of common salt, and has treated about 40 cases of ordinary epilepsy in this way. Several patients, especially such as have come under treatment in youth, have been completely cured. They have taken the bromides for about two years after the last attack, and have since remained well. Others are on the way to recovery. Almost all have been at least much improved.

In the bad cases it was not possible to avoid the two rocks, as the attacks, even if weakened, still persist with doses that set up a disagreeable and disquieting brominism.

ing brominism.

It is of the greatest importance not to neglect the epileptic attacks, they must be treated in a timely and effective manner. If they are taken at once the chances of recovery are great; if, on the other hand, the cases

are neglected, they will eventually become incurable. Experience teaches that.

Absolute deprivation of salt is dangerous; a relative deprivation is sufficient. If disquieting symptoms come on from too large doses of bromides or from complete withholding of salt, a little relaxation of stringency as regards both points will bring things right again. But we should not get frightened and give up the case as hopeless.

Prof. Forel orders the bromides in the following manner:—Potassic brom., sodium brom., ammon. brom., of each 300 to 400 grammes. Well ground and mixed. The patient procures a small pair of apothecary's scales with  $\frac{1}{2}$ , I, and 2 grm. weights, the patient to weigh out every evening the quantity for next day and dissolve it in a litre or more of Dezilit water, one-third to be taken on rising, one-third three-quarters of an hour before the midday meal, and the remainder the same length of time before the evening meal.

# AUSTRIA. Vienna, Jun: 6th, 1909.

THE GROWTH OF CRETINS. JAUREGG gave an account of his results with the thyroid gland on the growth of cretins at the Gesellschaft der Aerzte. He finds the growth in this class increases more rapidly during the first year of treat-ment, and the younger the patient the more effectual the result. In the first year 12 centimetres is the average—i.e., 4.7 in.; after that period the growth is variable, and it is still questionable if we can ever get the patient to the average normal height. There is no doubt the growth can be kept up till puberty, but the rate of increase is so irregular that the normal height is never attained in the cretin. The age of puberty need not deter anyone from the use of thyroid, as he has commenced the treatment at the age of 23 years, with 121 centimetres growth after. Even after the age of 30 years he has had a growth of 4 centimetres. About this age the growth stops quite suddenly, not to move again, while at any other age it stops gradually, or wavers, when it reaches the extreme point. As a rule the cretin moves off under treatment 2 to 3 centimetres the first half-year, but only 1 a centimetre during the second half. This seems to be a fixed law in the treatment; the gland either loses us stimuli or the organism gets more resistant to the effects of the drug, and neutralises the force of growth. Wagner thought the latter was the case, as the drug had no effect on growth where the disease was nonthyrogenic in origin; furthermore, the treatment may be continued for any length of time without injury or any other bad effects on the organism. The explanation seems to be that the drug confines its action to the thyroid gland, and where this is not at fault the results are nil; but if endemic goitre or any of the allied conditions be present, the action is prompt at d effectual. If it does not respond early in cretins even when the thyroid is enlarged, it is useless to persevere in its administration; even in simple functional disturbance of the gland the same rule is valid.

SPONTANEOUS AMPUTATION OF THE APPENDIX.

Friedländer gave the history of a case where the vermitorm process became detached. This was a case of appendicitis which he operated on, but found only a few fragments of the obsolete organ, which were carefully removed, and the wound closed. After this the patient quite recovered, and felt as well as ever. Again the symptoms of appendicitis re-appeared with the more grave signs of perforating peritonitis, for which another operation was performed, and the abdomen freely opened when the appendix was found lying far removed from the original site. It appears that it got quite separated from the bowel in the first attack, and was carried into the abdominal cavity before the first operation, and thus escaped observation. It therefore behoves to operate early, and carefully note any transposition when the entire organ is not present.

Schnitzler recorded a series of analogous cases that had come under his own observation. In several cases with severe attacks of appendicitis with a pause and interval he has frequently found the vermiform entirely separated. On one occasion he found the

appendix in the pouch of Douglas, which by accretions resembled a good-sized pear. This is important to note, as many of our colleagues affirm that this becomes absorbed after being detached, as in the cases cited. This is not always true, and should be carefully examined when any intervals of pause occur.

MORBUS ADDISONII.

Pollak presented a typical case of the disease which had existed for two years. One milligramme of adrenalin did not produce glycosuria, but the lowered function of the chrom. affinity is exalted. On the other hand, if the patient suffers from thyreoidea, I milligramme of adrenalin will produce sugar. It appears there is an additive action or a co-relative function between the adrenalin and the gland.

Porges related other similar cases of morbus Addisonii, where 300 grammes of grape sugar were given, and no glycosuria was produced by the gland when 1 milligramme was injected. There may be some significance in the amount of sugar found in the blood of Addisonii patients. In those which he had examined he found 0.055 and 0.04 per cent. of sugar present, with a blood pressure of 80 millimetres of mercury. In doubtful cases this high percentage of sugar is diagnostic.

## FROM OUR SPECIAL CORRESPONDENTS AT HOME.

#### BELFAST.

Belfast Union—Dufferin Children's Hospital.—Last Friday afternoon the new children's infirmary at the Belfast Union was opened by Lady Hermione Blackwood. The building has been designed on the most modern hospital principles, and is a credit to all concerned. It is of red brick, three storeys high, with eight wards to accommodate 200 children. There are large balconies, where the children may enjoy the fresh air in good weather, and both balconies and windows are carefully guarded to prevent accidents. Arrangements have been made by which the wards can be isolated from each other, each ward having its own lavatory accommodation, etc., complete. Lady Hermione Blackwood was welcomed by the chairman of the Board of Guardians, Dr. J. S. Bryars, and at the conclusion of the opening ceremony a vote of thanks was moved by Sir John Byers, M.D.

FEVER TRAINING FOR NURSES.—Up till now the

rever training for Nurses.—Up till now the nurses in the Fever Hospital at Purdysburn have been drawn from the Belfast Union, but a move is on foot to throw open the door to nurses from other hospitals. Applications have been received from the Royal Victoria and the Mater Infirmorum Hospitals, asking that their nurses may have the benefit of training in fever cases, and a special sub-committee of the Public Health Committee has been appointed to confer with the Medical Officer, Dr. Gardner Robb, and draft a scheme.

Sanitary Conditions of Irish Factories.—Considerable interest has been roused by the severe criticisms of Irish factories, chiefly in the North, contained in the anunal report of the Chief Inspector of Factories and Workshops for 1908, just issued. Miss Martindale, the very active and efficient lady inspector, whose services medical men value highly, discloses a very bad state of affairs in many factories. The sanitary accommodation for women and girls is often shocking, and dangerous to health. Two large factories were found in which there was not even a "make-believe" method of warming in winter, even though the factory had been built fairly recently in one case. In March the inspector found the temperature of the rooms in one factory varied from 45° to 54°, and samples of air taken showed as much as 32.8 parts of CO2 per 10,000. In one room with 56 women, the Medical Inspector, Dr. Legge, found over 50 per cent. suffering from anæmia, and as the cases of anæmia were chiefly among those who had worked longest in the factory, the cause was fairly obvious. The inspector took into Court the death certificates of four girls who had been strong, healthy girls previous to working in the factory, with good family history, yet after a few years' work all four had died of phthisis. The

case ended in a conviction, with a penalty of £1 and £5 costs—a most important verdict from the point of view of those interested in the prevention of tuberculosis in Ireland. Miss Martindale is very severe in her strictures on the employment of children, and rightly so. Fancy such a case as one she reports, a child who had practically never attended school owing to delicate health, and yet a week after she was 14 she was sent to a factory where she had to stand the entire day at work. Public opinion in these matters, she says, is in Ireland far behind that in England. She prosecuted a firm on behalf of five little girls who had been employed full time since they were 9 or 10 years old. "It is impossible for me to describe the antagonism aroused in the whole district by this prosecution. Everyone was against me, and the case was dismissed on a small technical point." In concluding her report she adds:—"I have no hesitation in saying that until public opinion is roused the children of the Irish industrial classes will remain weakly and undersized, the high death-rate will continue, and the children will grow up as illiterate as their innate brightness and cleverness will allow."

QUEEN'S UNIVERSITY, BELFAST.—Deep sympathy is felt with the popular Professor of Anatomy, Dr. Symington, at the death of his wife in Edinburgh, where she had gone on a short visit to her relations. The funeral was attended, on behalf of the College staff, by Professors Morton, Gregg Wilson, T. Milroy, and Dr. John Milroy.

and Dr. John Milroy.

Dr. P. T. Crymble has been elected the first holder of the Mackay Wilson Travelling Medical Scholarship, valued at £100 per annum, and has gone to Vienna to carry on his studies there.

#### LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE NAUHEIM TREATMENT OF DISEASES OF THE HEART AND CIRCULATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the gratifying review of my little book, which appeared in THE MEDICAL PRESS of May 26th, you adversely criticise the last chapter in the following words:

"We must confess that the last chapter, which contains the records of cases successfully treated, does not seem to us to favour the author's contention, for some of the diagrams which illustrate the reduction of the cardiac dulness appear to show that the heart's dimensions after treatment are much smaller than normal. Yet cardiac atrophy, if it could be induced, would scarcely be beneficial. Again, in Case No. 4, that of a patient said to be the subject of aortic stenosis and mitral regurgitation, we should have thought that the presence of the apex beat within the nipple line after treatment, and the pulse tracing given, which shows a sharp apex and a distinct dicrotic notch, would of themselves refute the diagnosis."

I am sure you will allow me a little of your valuable space to answer this criticism.

Firstly, all medical men are aware that the expression "normal cardiac dulness" really means "usual cardiac dulness," and that it is not uncommon to meet with cases of healthy people in which the cardiac dulness is smaller than "normal," although no emphysema of the lungs, or other pathological condition, is present. The shape of the chest, in my opinion, has a very definite bearing on the "normal" cardiac dulness of any one case.

Secondly, several of the cases in Chapter IV. are

Secondly, several of the cases in Chapter IV. are those of women, and in three of these the breasts were large and flabby, and the position of the nipple was by no means an exact anatomical position, but the mid-sternal line and the nipple are the only points that can be satisfactorily indicated in a tracing.

Thirdly, Case No. IV. was that of a woman with large breasts, and the nipple in this case did not indicate a definite anatomical position, and the heart was decidedly hypertrophied. I gave this patient the treatment 15 years ago, and I have just heard from her

medical attendant. He says :-- "She died four or five years ago from hemiplegia, and the cardiac condition was as you have stated."

The intention of the diagrams of cardiac dulness is to illustrate the comparative sizes of the heart before and after treatment, and I contend that they do illustrate this as accurately as any diagrams of a percussed cardiac dulness could do.

As I pointed out in Chapter I., the decrease in cardiac dulness in a case of cardiac dilatation is only

one sign of an improved condition, the general improvement in the health of the patient being a most important indication of a better and more normal state of the heart and circulation, but the improvement in the health of a patient cannot be shown diagrammatically, and the area of cardiac dulness can. It is for this reason that I use these diagrams, and not because I regard them as absolutely accurate anatomical drawings.

Should a further edition of my book be published,

I will not omit to point out the above facts.

In conclusion, I would thank you for your criticism, which has shown me a defect in my book, and has drawn my attention to the fact that the absence of an explanation of the diagrams in the last chapter justifies your criticism.

I am, Sir, yours truly,
LESLIE THORNE THORNE.

53 Queen Anne Street, W., May 29th, 1909.

#### LOCAL GOVERNMENT AND NATIONAL WELFARE

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—The Times of May 20th publishes one of its usual able articles on the supplement to the Annual Report of the Local Government Board. There is very little new to be said upon the question of the scandalous maladministration of sanitary laws which prevails so widely in many districts, but the *Times* repeats its criticism in the usual incisive fashion, without, however, suggesting any remedy for the abuses it exposes The Times finds its chief text in that portion of the report which deals with a number of "urban" districts in the West Riding of Yorkshire. The majority of these so-called urban districts are mainly rural in character; they acquired their urban status under the Local Government Act of 1858, the object being to evade the payment of the county high-way rates. The *Times* points out that, as one result, the roads are very badly kept, but, what is more important, it shows that the salaries paid to Medical Officers of Health are grossly inadequate, and that in most of the districts the sanitary inspector devotes only a fraction of his time to his work, usually combining other occupations with his sanitary appointment, and being in many instances merely a foreman 10ad-mender or a tax-collector. The Medical Officer is under the daily temptation, or necessity, to sub-ordinate the sanitary interests of his district to the maintenance of good relations with his masters, the Authority. It is as much as his place is worth to suggest any action likely to be displeasing to them; they can dismiss him virtually at their caprice; they can dock his paltry stipend; they can refuse to raise it, or give him a retiring allowance on completion of long and faithful services. In a letter which you did me the honour to print a few weeks ago, I pointed out that our attempts at democratic government have so far turned out a failure, and I cited the recent utterarces of Mr. John Burns in advocacy of a return to bureaucratic methods. The only cure for existing evils lies in the election to the authorities of superior men; but superior men won't come forward in face of the apathy displayed by all the classes upon whom the duty of citizenship should be most obligatory. The petty troubles of the underpaid medical officer are, however, as nothing compared with the injury to the State which the present condition of things involves. Within the last few days Dr. Karl Pearson has demonstrated the fact that if our birth-rate continues to decline at its present rate, we shall, in about twelve years, be in the same position as France, with no surplus population. This will mark a final stage in the decadence of the British Empire. Its existence can be prolonged only if our people are physically, mentally, and morally superior to our mighty neighbours in Europe and Asia. It was lately pointed out by one of your correspondents that Germany nas twenty millions more at home than we count in these islands. If by neglect of the teachings of science we allow ourselves to remain as a mass on a lower level of civilisation, there can be no doubt that in time the dominion of the world will fall to the nations with exuberant and virile populations, unspoilt by egoistical vices which are causing the destruction of some of the erstwhile leading peoples of the Western world. The social problem, in the widest sense of the word, is the vital problem. Are our statesmen giving it the attention it so urgently calls for? I, for one, think they are not.

M. O. H.

May 29th, 1909.

#### MEDICAL MISSIONS.

To the Editor of The MEDICAL PRESS AND CIRCULAR SIR,—I rejoice exceedingly at the words spoken at the commemoration day of the Livingstone College as reported in your last issue. When, in 1879, I was impressed by the wretched state of the women and children in "Greater Britain," i.e., India, Ceylon, Africa Burna at besides in those Factors and Africa, Burma, etc., besides in those Eastern parts, not British, where I had been; and when I came to know that often missionaries—men and women—went as messengers of Christianity as regards the soul, but medically ignorant as regards the body-their own as well as those to whom they went—and unable to minister to it, my spirit was stirred within me, and I started the Zenana Medical Mission College. The successes of those women who were trained, and have gone out, as missionaries, amply compensated for the opprobrium heaped on us at the time, and for the time, labour and means bestowed upon the work, and for the discouragements offered by those to whom we looked for encouragement. I wish your pages permitted me to tell of some of the successes of our pupils. and the commendation bestowed upon their while in training, and upon their labours when abroad. "Valuable lives might have been saved if the persons had had the advantage of modern training," said the Master of Trinity, Cambridge University, my cle friend and former fellow student in Dublin. Your report further states: - Prof. Alex. Macalister said: "Doubts had been expressed as to the wisdom of the training given; he thought that these doubts had long since been laid aside, and as an old medical teacher he had complete confidence in the course of training From his experience in many parts of the world especially in Syria and China, he believed that it was a necessity for a missionary to be able to render simple medical aid to the natives, and, in the absence of qualified medical aid, it was most important that ordinary missionaries should have elementary medical training, as is given at Livingstone College. He hoped that before long some such training would be regarded as an absolute necessity for every missionary." I am glad of the success of the Livingstone College for Men, and in the continued successful work amongst women and children of the Zenana Medical Mission College and Hospital.

I am, Sir, yours truly,
G. DE G. GRIFFITH.

London, June 4th, 1909.

#### OBITUARY.

GEORGE HENRY HAMES, F.R.C.S.

WE regret to announce that the death has taken place at Park Lane of Mr. G. H. Hames, who practised in

Mayfair for the past twenty years.

Mr. Hames was medically educated at St. Bartholomew's Hospital and at the Rotunda Hospital, Dublin At St. Bartholomew's Medical School he won both the Kirke Scholarship and gold medal and the Brackan-bury Medical Scholarship in 1875. He was also 2 Foster prizeman. At the hospital he had been both

House Surgeon and House Physician, and had held resident appointments at the Cheyne Hospital for Children and at the Western General Dispensary. Hames qualified as a Licentiate of the Royal College of Physicians in 1876, and as a Fellow of the Royal College of Surgeons in 1878, where he had previously been Prosector. For some years he was the Honorary Secretary of the London Abernethian Society.

#### MILITARY & NAVAL MEDICAL NOTES.

NAVAL medical officers will regretfully hear of the sudden death of Mr. H. W. Temple, I.S.O., who was head of the clerical staff of the Medical Department of the Admiralty. He had almost completed forty years' service, and was to have retired shortly. The Naval and Military Record says he was well known to all naval medical officers, by whom he was held in much respect.

LT.-COL. W. B. BANNERMAN, M.D., B.Sc., I.M.S., has been granted the degree of Doctor of Science in the Department of Public Health, Edinburgh University. The subject of his thesis was "The Action of the Bacillus Pestis on Certain Carbo-Hydrates and Allied Bodies in Liquid Media for the Manufacture of Anti-Plague Vaccine." The officer above-named is the Director of the Bombay Bacteriological Laboratory and Consulting Bacteriologist to the Grant Medical College.

THE Naval and Military Record says that a vacancy on the Surgeon-General's list of the Army Medical Service will occur shortly, when Surgeon-General W. L. Gubbins, C.B., M.V.O., M.B., retires under the age rules. This announcement may be correct, but it is generally reported that this officer's service is to be extended so as to enable him to succeed to the Director-Generalship of the A.M.S., when the present occupant vacates at the end of the present year, or early in March, 1910. The report which is in circulation is given with a sort of "cocksureness" which savours of great probability.

IF we desire to know the unfortunate disappointments and uncertainties of employment, or conditions of employment, in our public services, we cannot do better than study a question and its answer in the House of Commons on "The Egyptian Sanitary Service," Sir E. Grey's answer to Mr. Ramsav MacDonald, M.P. for Leicester, is of the usual shuffling nature. It is difficult to form an opinion of the rights and wrongs of the individuals figuring in the report of the Times, but a very clear warning may be given to those about to enter public services to make sure of their positions, if that is possible, in any public service.

THE DUKE OF YORK'S Royal Military School at Chelsea will be moved to Dover during this year. The history of the move is simply this: A committee of medical experts some time ago pronounced the buildings now occupied as insanitary and unfit for longer occupation as a school. Any alterations to bring it up to date would have cost a large sum. Much opposition to the removal was shown in the public Press, no doubt attributable to the local interests of shop-keepers being affected, and also to the antiquated and highly conservative views of out-of-date people, military and civil. There can be no doubt that in a moral and material point of view the change to Dover is correct, and this, no doubt, will be proved hereafter by greater health and energy among the young lads, chiefly soldiers' sons, who are in the school.

It has been decided that medical officers gazetted to the Territorial R.A.M.C. shall wear R.A.M.C. uniform, but with silver lace and ornaments, unless appointed to units which have permission to wear gold lace. Regimental medical officers who served with Yeomanry and Volunteer Corps, and who have

not joined the R.A.M.C., may, if still serving with their old or reconstituted units, continue to wear regi-mental uniforms with R.A.M.C. belts. Veterinary officers gazetted to the Territorial unattached list will officers gazetted to the Territorial unattached list will wear Service dress of universal pattern. They may also wear Army Veterinary Department full dress uniform, but with silver lace and ornaments. Those having uniform of their former Yeomanry or Volunteer Corps may wear it in addition to Service dress until the end of 1910.

THE following information, given by the Army Service Corps Journal, will be interesting to military and naval medical officers:—"During the late manœuvres in Egypt, at the base of each force-Helouan and Khanka-field bakeries were erected, and all the bread for the troops was baked at these places. The cattle were driven on the hoof and prepared for consumption at each camp. Though the railway was available at practically every camp, this mode of conveyance was entirely discarded, it being assumed that the railway was non-existent. Camels were used for all transport services. A very interesting experiment was made by sending a quantity of frozen meat by camel, a distance of 88 miles. On its journey the temperature attained a height of 88°. The meat was inspected and issued on arrival, and was found to-be perfectly fresh and palatable."

#### SPECIAL ARTICLES.

#### THE NATIONAL UNIVERSITY OF IRELAND.

THE Dublin Commissioners appointed under the Irish Universities Act, 1908, to make Statutes for the general government of the University which has since been incorporated under the name of the National University of Ireland, have made the Statutes for the general government of the University and its constituent Colleges.

The degrees in the Faculty of Medicine will be:—

Bachelor of Medicine (M.B.), Bachelor of Surgery (B.Ch.), Bachelor of Obstetrics (B.A.O.), Bachelor (B.Ch.), Bachelor of Obstetrics (B.A.O.), Bachelor of Science, Public Health (B.Sc., Public Health), Master of Surgery (M.Ch.), Master of Obstetrics (M.A.O.), Doctor of Medicine (M.D.), Doctor of Science, Public Health (D.Sc., Public Health), Bachelor of Dental Surgery (B.D.S.), Master of Dental Surgery (M.D.S.).

Dental Surgery (M.D.S.).

In University College, Dublin, in the Faculty of Medicine there will be the following Professorships and Lectureships at the appended stipends:—\*The Professorship of Chemistry, £750; \*the Professorship of Experimental Physics, £800; \*the Professorship of Zoology, £600; \*the Professorship of Anatomy, £800; \*the Professorship of Pathology and Histology, £700; \*the Professorship of Hygiene and Medical Jurisprudence, £250; the Professorship of Materia Medica and Therapeutics, £200; the Professorship of Medicine, £250; the Professorship of ### And The Professorship of Medicine, £250; the Professorship of Midwifery and Gynæcology, £200; the Professorship of Surgery, £300; \*the Lectureship in Physics, £300; \*the Lectureship in Botany, £350; the Lectureship in Ophthalmology, £50; the Lectureship in Dental Mechanics, £50; the Lectureship in Dental Surgery, £50; the Lectureship in Special Pathology, £250.

Pathology, £250.

In University College, Cork, the Professorships and Lectureships will be: — \*The Professorship of Chemistry, £600; \*the Professorship of Scology, £550; \*the Professorship of Anatomy, £600; the Professorship of Medicine, £200; the Professorship of Obstetrics and Gynæcology, £200; \*the Professorship of Obstetrics and Gynæcology, £200; \*the Professorship of Physiology, £600; the Professorship of Surgery, £250; the Professorship of Therapeutics, £100; the Lectureship on Hygiene, £50; the Lectureship on Medical Jurisprudence, £50; the Lectureship on Mental Diseases, £50; the Lectureship on Ophthalmology, £50. mology, £50.
In University College, Galway, the Professorships

and Lectureships will be:—\*The Professorship of Physics, £350; \*the Professorship of Chemistry, £350; \*the Professorship of Natural History, Geology and Mineralogy, £350; \*the Professorship of Anatomy and Physiology, £350; the Professorship of Medicine, £150; the Professorship of Surgery, £150; the Professorship of Obstetrics and Gynæcology, £150; the Professorships of Materia Medica and Pharmacy, £150; the two Lectureships on Medical Jurisprudence and the two Lectureships on Medical Jurisprudence and Hygiene, £40 each; the Lectureship on Fever cases,

£20. [Professorships and Lectureships in the above list to which an asterisk is prefixed shall be considered to be, and shall be, Full Time Professorships and Lecture-

#### MEDICAL NEWS IN BRIEF.

#### Royal College of Surgeons in Ireland-Annual Election.

THE annual meeting of the Fellows was held on Saturday last, June 5th, the President, Mr. J. Lentaigne, in the chair. A favourable report was submitted. During the year 19 candidates, having passed the examination, were admitted Fellows; 48 obtained the Licence, 27 the Diploma in Public Health; 16 the Licence in Dental Surgery, and 70 passed the entrance examination. The obituary list showed that 8 Fellows and 28 Licentiates died during the year. There are at present living 484 Fellows, 2,910 Licentiates, 303 Diplomates in Public Health, and 538 Licentiates in Dental Surgery.

At a meeting of the Fellows held on Monday, June 7th, the following were elected for the ensuing

President.—John Lentaigne, F.R.C.S. Vice-President.—Robert H. Woods, F.R.C.S. Secretary of the College.—Sir Charles A. Cameron,

C.B., F.R.C.S.

C.B., F.R.C.S.

Council.—Sir Henry R. Swanzy, F.R.C.S.; William Stoker, F.R.C.S.; Sir Charles Alexander Cameron, C.B., F.R.C.S.; John B. Story, F.R.C.S.; Sir Charles B. Ball, F.R.C.S.; Sir Thomas Myles, F.R.C.S.; Sir Arthur Chance, F.R.C.S.; Richard D. Purefoy, F.R.C.S.; Sir Lambert H. Ormsby, F.R.C.S.; Henry G. Sherlock, F.R.C.S.; R. Bolton M'Causland, F.R.C.S.; R. Lane-Joynt, F.R.C.S.; William Taylor, F.R.C.S.; Edward H. Taylor, F.R.C.S.; G. Jameson Johnston, F.R.C.S.; R. Charles B. Maunsell, F.R.C.S.; William Ireland Wheeler, F.R.C.S.; D. Edgar Flinn, F.R.C.S.; Thomas E. Gordon, F.R.C.S.

#### A Medical Visit to Harrogate.

DR. DR MOUILLOT, of Harrogate, as President of the Irish Medical Schools' and Graduates' Association, invited a number of prominent members to pay a week-end visit to this favourite health resort, the Mayor, Alderman Balmforth, and many members of the Harrogate Medical Society, joining heartily in the reception and entertainment of the visitors. On Saturday Dr. Sibley arranged and conducted an excellent concert on their behalf, after which Dr. and Mrs de Mouillot held a reception in the Kursaal grounds, where tea was served. In the evening a banquet was held at the Majestic Hotel, the President of the Association occupying the chair. He was supported by the Mayor and Mayoress, and, among others, by the following members of the profession and their ladies:—Drs. J. G. Black, Shepherd Boyd, Hind, and C. Gibson, J.P., Harrogate; Dr. Crawford Watson (President of the Harrogate Medical Society), Dr. E. Solly (President of the Balneological Society), Dr. H. Macnaughton-Jones (London, Vice-President), Dr. Macan (Cheam, Chairman of the Council), Dr. Michael J. Bulger (London, Hon. Treasurer), Dr. Thos. H. Crampton and Dr. Geo. Wm. Dawson (London, Hon. Secretaries), Dr. P. Abraham and Dr. Fegan (London), Dr. Peters, Dr. Lever, Dr. Nimmo de Mouillot held a reception in the Kursaal grounds, Fegan (London), Dr. Peters, Dr. Lever, Dr. Nimmo Watson, Dr. Bertram Watson, Dr. A. W. Hinsley Walker, Dr. J. B. Story and Dr. Delahoyde (Dublin), Dr. Fitzgerald, Dr. Campbell Boyd, Dr. D. Wilson, Dr. Franklin, Dr. H. Thompson, Dr. Wilkinson, Dr. Robinson, Dr. Beardsley, Dr. McKee, Dr. Mantle,

Dr. Wills, Dr. Pringle, Dr Ross, Dr. Brown, Dr. Morris, Dr. David Browne, Dr. Bain, Dr. Laura Veale, Dr. and Mrs. Edgecombe, Dr. Atkinson, Dr. O'Brien, Dr. Rutherford, Dr. Liddell, Dr. Pronger, Dr. Jacobs, Dr. Thompson, Dr. Garrad, Dr. Campbell Ward, Mr. J. Turner Taylor (Town Clerk). Considerable anthusian was availed in the creather as to interest the contraction of the able enthusiasm was evoked in the speeches as to the remarkable resources and beauties of Harrogate as a health resort, and as a bathing centre second to none in Europe. The toast of the Harrogate Medical Society was proposed by Dr. Macnaughton-Jones and responded to by Dr. Crawford Watson, and that of the President by Dr. Solly. On Sunday the visitors were taken in automobiles to various places of in-terest, and altogether the visit proved of exceptional interest.

#### Death from Cocaine.

AT Newcastle Infirmary on June 2nd, the City Coroner resumed an inquest on J. T. Lauderdale, 2ct. 19, draper's assistant When the inquest was opened it was stated that Lauderdale went to the Infirmary to be operated on for a growth in his right nostril. Otherwise he was in good general health.

Mr. Walker, House Surgeon, said the operation was to have been performed at noon on Saturday. At 11.30 Lauderdale's nostrils were packed with lint soaked in cocaine hydrochloride to act as a local About ten minutes afterwards the deanæsthetic. ceased walked into the operating room and the doctor asked him how he felt. He replied that he was all asked him how he felt. He replied that he was all right. Witness left the room for a few minutes. When he returned, the deceased's breathing was laboured, and he had four convulsive fits and died. Witness thought death was due to the cocaine becoming absorbed in the mucous membrane of the nose which had the effect of producing convulsions and respiratory troubles.

Dr. George Hall, pathologist to the Infirmary, who made a post-mortem examination, said all the signs pointed to death through asphyxia, probably caused

by the action of the cocaine.

Answering the Coroner, Dr. Hall said he did not think the delay of twenty minutes between the administration of the cocaine and the operation was an unreasonable time.

Nurse Pattinson said it had been the practice for the sister and staff nurses to give local anæsthetics in minor cases. She had never previously seen a case of collapse.

The jury returned a verdict in accordance with the

medical evidence.

#### Lord Lonsdale and Vivisection.

MISS LIND-AF-HAGEBY, hon. general secretary to the International Anti-Vivisection and Animal Protection Congress, writes in reply to Lord Lonsdale's statements as to his attitude towards vivisection, quoted in The Times of May 26th :-

"Lord Lonsdale has held the position of hon. treasurer to the congress for five months, and his present action comes as a complete surprise to the committee. . . . In inviting Lord Lonsdale to become the hon, treasurer of the congress the organising committee bore in mind that he has for several years been a vice-president of the Incorporated Parliamentary Association for the Abolition of Vivisection, and that he recently gave £100 to that association, for the activities of which he has expressed sympathy. On November 20th last he expressed his pleasure at becoming the hon. treasurer of the Anti-Vivisection and Animal Protection Congress, and later on promised to subscribe £50 to the special congress promised to subscribe £50 to the special congress fund. On May 20th Lord Lonsdale signed a public letter of appeal, completely identifying himself with anti-vivisection, and referring to the great moral, social, and scientific importance of the issue for which we fight.' . . . The officials and committee of the congress can accept no responsibility for Lord Lonsdale's incomprehensible changes of mind, or for the presence of his signature upon the letter of appeal for assistance to a cause which, as it turns out, had in him so weak a champion."

The public letter of appeal referred to by Miss Lind-af-Hageby as having been signed by Lord Lonsdale contains the following statement:—"The width of our scheme and its inclusion of other forms of animal protection will strengthen rather than weaken the anti-vivisection work of the congress and will constitute a practical protest against the efforts of vivisectors to exclude scientific cruelty to animals from the ban placed upon ordinary cruelty."—Times.

#### The New Milk Bill.

THE important Milk and Dairies Bill [Bill 216] introduced by the President of the Local Government Board and read a first time in the House of Commons on the 25th ult., has now been printed. It has as its main objects (1) the more effective registration of dairies and dairymen; (2) the inspection of dairies and the examination of cows therein; (3) the prohiand the examination of cows merein; (3) the promi-bition of the supply of milk from a dairy where such a supply has caused or would be likely to cause infectious diseases, including tuberculous; (4) the prevention of the sale of tuberculous milk; (5) the regulation of the importation of milk so as to prevent danger to public health arising therefrom; (6) the issue of regulations for securing the supply of pure and wholesome milk; (7) the establishment by local authorities in populous places of milk depôts for the sale of milk specially prepared for infants.

#### Medical Motorists and the Budget.

MR. C. B. LOCKWOOD, F.R.C.S., of St. Bartholomew's Hospital, occupied the chair at a special meeting of the Motor Union Committee of Medical Motorists. at the offices of the Union a few days ago to consider the Budget proposals of the Chancellor of the Exchequer in so far as they affect members of the medical profession using motor-cars. There was a representative attendance of medical men, members having travelled from the North and West of England in order to be present at the meeting. The committee resolved that the motor-car has now become an absolute necessity to a medical practitioner who is therefore en sity to a medical practitioner, who is, therefore, entitled to make a special claim for abatement. It was resolved to approach the Chancellor of the Exchequer with a view to securing a rebate of 1½d. per gallon on petrol used by medical men. A letter was read from Mr. W. Joynson Hicks, M.P. (chairman of the Motor Union), stating that the Chancellor had agreed to receive a deputation on the matter.

#### State Grant in Aid of Scientific Investigations.

In connection with the annual grant voted by Parliament in aid of scientific investigations concern-

rariament in aid of scientific investigations concerning the causes and processes of disease, Mr. Burns, the President of the Local Government Board, has authorised the following special researches:—

1. A continuation of the investigation into protracted and recurrent infection in enteric fever, by Dr. Theodore Thomson, Medical Inspector of the Board, in conjunction with Dr. Hedingham, of the Lister Institute.

2. A continuation of the investigation into pro-tracted and recurrent infection in diphtheria, by Dr.

Theodore Thomson and Dr. C. J. Thomas.

3. A continuation of the investigation into flies as carriers of infection by Dr. Monckton Copeman, Medical Inspector of the Board, and by Professor Nuttall, of Cambridge.

A continuation of Dr. Andrewse, investigation on

4. A continuation of Dr. Andrewes' investigation on the presence of sewage bacteria in sewer air, with a view to ascertaining their number and the distance they can be carried by air currents. Also a continuation of Dr. Andrewes' investigation into the part played by changes in bone marrow in the defensive mechanism of the hody against infection

mechanism of the body against infection.

5. A continuation of Dr. Savage's investigation on the bacterial measurement of milk pollution, and on the presence of the Gaertner group of bacilli in prepared measurement of milk pollution.

6. An investigation into the chemical and physical changes undergone by milk as the result of infection by bacteria, and into the relation of the pancreas to epidemic diarrhea, by Dr. Schölberg and Mr. Wallis, of University College, Cardiff. 7. An investigation of the records of charitable lying-in hospitals as to the nutrition of the mother and other factors influencing the vitality of infants and their progress in the first fourteen days of life, by Dr. Darwall Smith, Physician to the British Lyingin Hospital.

8. An investigation into the occurrence and importance, in relation to treatment, of mixed infections in pulmonary tuberculosis, by Dr. Inman, pathologist to the Brompton Hospital for Consumption.

9. An investigation on the relative importance of certain types of body-cells in defence against the tubercle-bacillus, and the effect of tuberculin and other remedial agents on their activities, by Dr. J. Hiller, Pathologist to the General Hospital, Birmingham.

#### PASS LISTS.

University of London.

THE following candidates passed the M.B., B.S.

xamination during May:

Honours Division.—Albert Harold Godwin Burton Honours Division.—Albert Harold Godwin Burton (c), Guy's Hosp.; Reginald Robert Elworthy (a), Westminster Hosp.; Augustin Pownall Fry (d), St Bartholomew's Hosp.; Manchersha D. D. Gilder (d), University College Hosp.; Cecil Augustus Joll, B.Sc. (a, b, c, d, University Medal), Univ. Coll., Bristol; Dan Arthur Powell (a), Charing Cross Hosp. (a) Distinguished in Medicine. (b) Distinguished in Pathology. (c) Distinguished in Forensic Medicine and Hygiene. (d) Distinguished in Surgery.

Ordinary Pass.—Leonard T. Baker, Guy's Hosp.;

Hygiene. (a) Distinguished in Surgery
Ordinary Pass.—Leonard T. Baker, Guy's Hosp.;
Stanley J. Beale, London Hosp.; Trevor L. Bomford,
St. Bartholomew's Hosp.; Robert H Bott, St. Bartholomew's Hosp.; Karl Bremer, St. Bartholomew's
Hosp.; Charles H. Broomhead, Victoria Univ., Manchester;
Elsie M. Chubb, Lond. (R.F.H.) Sch. of Med. for

QUARRENS.—Hydrocystoms is a harmless retention cyst of the sweat-ducts. It occurs chiefly in the face of women who perspire freely (said to be especially common in laundresses). The cysts are discrete, of a size from that of a pin-head to a pea. Puncture, and use a dusting powder.

and use a dusting powder.

DR. DABBS ON THE BUDGET.

Our confrère, Dr. G. H. R. Dabbs, in the June issue of his journal, is a little cynical about the Budget and its author. He says he might write a great deal about the subject, but refrains from doing so, as the matter has already been summed up so wittily by another with the simple quotation from an old nursery rhyme: "Taffy was a Welshman, Taffy was a —" Rus IN URBE.—The law of libel is in a most unsatisfactory condition, but we cannot gather from the letters submitted to us that you have written anything actionable. As you are a member of the Medical Defence Union, you had better write at once to Dr. A. G. Bateman for advice.

FREE MEDICAL PUPILAGE FOR A LADY.

once to Dr. A. G. Bateman for advice.

FREE MEDICAL PUPILAGE FOR A LADY.

A CORRESPONDENT, who is the hon. secretary to a well known
Zenana Medical Mission College and Hospital, in London, writes us
that friends of the institution have placed sufficient funds in his hands
to enable the College to take a free pupil for two years' training, so
that the lady selected would have none but her own personal expenses
to meet. Should any of our readers have a daughter or lady friend
anxious to undertake medical mission work, and will communicate an
once to the Editor of this journal, at the London office, he will put the
matter in the right channel.

Acquirect (Britist)—If you get a coloured glass oun (sold for

Aguracus (Bristol).—If you get a coloured glass cup (sold for the purpose), and place in front of the lens during exposure, you can equalise the colour values, and so get photographs of coloured skin conditions capable of reproduction.

#### Meetings of the Societies, Tectures, &c.

WEDNESDAY, JUNE 9TH.

UNITED SERVICES MEDICAL SOCIETY (Royal Army Medical College, Millbank, S.W.).—8.30 p.m.: Captain E. B. Waggett, R.A.M.C. (T.): The Mouth, Nose, Throat, and Ear from the Point of View of Recruiting.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. R. L. Evans: Clinique (Surgical). 5.15 p.m.: Lecture: Mr. F. Jaffray: Appendioitis—Symptoms and Diagnosis.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—Clinics: 2.30 p.m.: Medical Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks).

TRURSDAY, JUNE 10TH.

ROYAL SOCIETY OF MEDICINE (OBSTETRICAL AND GYNECOLOGICAL SECTION) (20 Hanover Square, W.).—7.45 p.m.: Specimens: Dr. G. E. Purslow: (1) Uterus, with Fibroid Tumour, from a Case in which Cessrian Hysterectomy was performed; (2) Bilateral Ovarian Tumcurs, One of which Obstructed Labour on Two occasions. Dr. W. J. Gow: Cancer Originating Separately in the Uterine Body and in the Cervix. Short Communications: Mr. J. Bland-Sutton: Red Degeneration of a Uterine Fibroid, associated with the Staphylococcus Pyogenes Aureus. Dr. G. Darwall Smith: An Unusual Solid Tumour of the Ovary. Dr. Blair Bell: A Case of Rudimentary Uterus Didelphys, with Ectopia of Each Uterine Body in an Inguinal Hernia Sac; with Some Remarks on the Development of the Female Genital Organs.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINODOM (1) Chandos Street, Cavendish Square, W.).—8 p.m.: Card Specimens will be shown by Mr. F. Fergus, Mr. F. W. Edridge-Green, Mr. A. Lawson, Mr. J. H. Fisher, and others. 8.30 p.m.: Mr W. H. H. Jessop: The Report of the International Committee on the Unification of the Notation of Visual Acuity and of the Meridians of Astigmatism. Mr. P. H. Adams: (1) A Family with Congenital Displacement of Lenses; (2) A Family with Congenital Opacities

of Lenses. Mr. A. H. Griffith and Mr. A. W. Ormond: A Case of Retinal Disease with Massive Exudation and Arterio-venous Communication. Dr. G. Mackay: An Epithelal Filament in the Anterior Chamber, Simulating a Thread Worm.

MEDICAL GRADMATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Sir Jonathan Hutchinson: Clinique (Surgical). 5.15 p.m. Lecture: Mr. J. Clarks: The Clinical Examination of Spinal Cases.

NORTH-EAST LONDON POST-GRADMATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynscological Operations (Dr. A. E. Giles). Clinics: Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. H. W. Carson); X-Rays. 3 p.m.: Medical In-patient (Dr. G. P. Chappel). 4.30 p.m.: Special Demonstration: Dr. T. R. Whipham: Cases of Children's Disease.

FRIDAY, JUNE 11TH.

FRIDAY, JUNE 11TH.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (11
Chandos Street, Cavendish Square, W.).—5 p.m.: Special Meeting.
Mr. Nettleship: Some Diseases of the Eye illustrating Heredity.
(Bowman Lecture.)
MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenics
Street, W.C.).—4 p.m.: Dr. D. Grant: Clinique (Ear, Nose, and
Throat).

CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray'S Inn Road, W.C.).—3.45 p.m.: Lecture: Mr. C. Nourse: Middle Ear Labyrinth.

#### Appointments.

BALT, A. L., M.R.C.S., L.R.C.P.Lond., First Assistant Medical Officer at the Lambeth Infirmary.

BIDIE, EVAN, L.R.C.P. and S.Edin., L.F.P.S.Glasg., Assistant Medical Officer at Wye House Asylum, Buxton.

BYGOTT, ALBERT HENRY, M.D.LOnd., D.P.H.Birm., Barrister-atlaw, Medical Officer of Health of Barking.

HAILES, C. D. G., M.D.Edin., F.R.C.S.Edin., Certifying Surgeon under the Factory and Workshop Act for the Bristol District of the county of Gloucester.

HALL, JOHN BASIL, M.B., B.C.Cantab., F.R.C.S.Edin., one of the Medical Referees under the Workmen's Compensation Act, 1906, for County Court Circuit No. 11, to be attached more particularly to Bradford, Keighley, Otley, and Skipton County Courts.

#### Bacancies.

Mercers' Hospital, Dublin.—Gynsecologist. Applications to the Registrar. (See advt.).

House of Recovery and Fever Hospital.—Junior Assistant Resident Medical Officer. Salary, £50, and board. Applications to the Medical Superintendent. (See advt.)

Lurgan Union.—Female Resident Medical Officer. Salary, £80 per annum, with extras. Immediate applications to James Calvert, Clerk of Union. (See advt.)

Bolingbroke Hospital, Wandsworth Common, S.W.—Resident Medical Officer. Salary, £150 per annum, with board and residence. Applications to the Hon. Sec. of the Medical Committee, Bolingbroke Hospital.

Birmingham General Dispensary.—Resident Surgeons. Salary, £170 per annum (with cab allowance of £30 per annum), and furnished rooms, fire, lights, and attendance. Applications to Ernest W. Forrest, Secretary.

Walsall and District Hospital.—House Surgeon. Salary, £100 per annum, with board and residence. Applications to Harold Wigg, Co.-Secretary.

Walsall and District Hospital.—Junior House Surgeon. Salary, £30 per annum, with board and residence. Applications to Harold Wigg, Co.-Secretary.

#### Births.

BASHFOED.—On June 4th, at 18 Downshire Hill, Hampstead, London, the wife of H. H. Bashford, M.D., of a daughter.
COOPER.—On June 5th, at Lansdowne, Hampton-on-Thames, the wife of Harold Merriman Cooper, M.B. (London), of a son.
DENYER.—On May 30th, at 26 Albion Street, Hull, Yorks, the wife of Stanley E. Denyer, C.M.G., M.D. Cantab., F.R.C.S. Eng., of a daughter.

Stanley E. Denyer, U.M.G., Salt. Canada, daughter.

KINNZER.—On May 21st, at Royton Hall, Royton, near Oldham, the wife of Forbea Kinnear, M.B., of a daughter.

WALKER.—On May 30th, at Hing-Hwa, South China, the wife of Dr. Donald R. Walker, of a son.

WHITE.—On May 5th, at Spring Grove, Louis Creek, North Thompson Valley, British Columbia, the wife (nee Ethel Palmer Budd) of Malcolm White, M.R.C.S., L.R.C.P., etc., of a son.

of a son.
WILSON.—On June 5th, at 22 Hilgreve Road, London, the wife of
J. Clark Wilson, M.D., M.R.C.P., of a daughter.

#### Marriages.

SHIPMAN—BOUSFIELD.—On June 2nd, at the Parish Church, Grantham, George Alfred Cargill Shipman, M.A., M.B., youngest son of Dr. G. W. Shipman, of Grantham, to Dorothy Louisa Bousfield, only daughter of the late Rev. Stephen Bousfield, M.A., Rector of Shelton, Notts, and Mrs. Bousfield, Grantham.

#### Beaths.

HARRISON.—On June 3rd, at 55 Hanover Gate Mansions, London, Jane, widow of Reginald Harrison, F.R.C.S., in her 70th year.

# ARTERIO-SCLEROSIS

#### PROPHYLACTIC PAR EXCELLENCE.

Experimental and Clinical Research has shown that this New Medicament is THE BEST for the Treatment of ARTERIO-SCLEROSIS.

Dose: Two Tablets thrice daily.

In Tubes of 32 Tablets.

Samples and Literature post free rem-

REITMEYER & CO., 63 Crutched Friars, E.C.

INDIEN

H Caxative, Refreshing, and Medicated Fruit Cozenge.

VERY AGREEABLE TO TAKE, AND NEVER CAUSING IRRITATION.

## hydiological action assures mandiate relief and . . . itual ours of . . . . . .

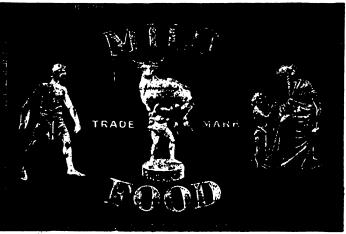

HÆMORRHOIDS, BILE, HEADACHE, LOSS OF APPETITE, AND INTESTINAL OBSTRUCTIONS.

By augmenting the peristaltic movement of the intestine without producing undue secretion of the liquids. Unlike pills and the usual purgatives, it does not predispose to intestinal sluggishness; and the same dose always produces the same effect—that is to say, never needs increasing.

It is recommended by the most eminent physicians of Paris, notably Drs. Bellin and Tardieu, who prescribe it constantly for the above complaints, and with the most marked success.

# **GRILLON.**

Wholesale-London: E. GRILLON, 87 Southwark Bridge Road, S.E. Sold by all Chemists and Druggists, 28, 6d, a box, stamp included

## A COMPLETE DIET FOR INFANTS.

MILO FOOD, being partly composed of milk, is complete and entire in itself, and requires simply the addition of water to make it ready for use. It is not merely an auxiliary, like other Infants' Foods, which require milk to be added in preparing for use.

Awarded the GOLD MEDAL at the CAPE TOWN EXHIBITION,

## Certificate of Merit by the Institute of Hygiene, London.

Examined, passed and exhibited by the INSTITUTE OF HYGIENE, at 34 Devoushire Street, Harley Street, W., where the Food can be seen and its value explained.

Sample and pamphlet on "The Feeding and Care of Infants" sent free on application to NESTLE and ANGLO-SWISS CONDENSED MILK CO., 6 & 8 Eastcheap, London, E.C.

# CAntihhloaistine

(Inflammation's Antidote.

For Abdominal Pain and Visceral Inflammation

A rational method of treating locally all forms of disease in which inflammation and congestion play a part.

The Denver Chemical Manufacturing Co., London.

# Hay Fever.

Clinical reports demonstrate that ADRENALIN is the most effective remedy in Hay Fever, ameliorating, almost immediately, the various distressing symptoms without undesirable sequelæ. Its powerful constringent action promptly reduces congestion, checks profuse secretion, and controls paroxysmal sneezing.

# ADRENALIN CHLORIDE SOLUTION 1:1000.

This solution, diluted with 10 to 20 volumes of physiological sodium chloride solution (1 Compressed Tablet Sodium Chloride, P., D. & Co., No. 365, dissolved in 4 fl. ounces of recently-boiled distilled water), may be sprayed into the nostrils or applied on pledgets of cotton-wool to the septum and the accessible portions of the lower and middle turbinates, and also instilled into the eyes.

A writer in the *British Medical Journal*, 4th July, 1903, p. 60, states that relief was obtained by using this solution when the paroxysm threatened.

Supplied in bottles of 1 fluid ounce and 10 c.c., also in ampoules of 0.5 c.c.

#### SOLUTION || ADRENALIN INHALANT.

This 1:1000 solution of Adrenalin Chloride in aromatised neutral oil containing 3 per cent. of Chloretone, secures more prolonged contact with the mucous membrane than does the aqueous solution. The antiseptic and analgesic properties of Chloretone are valuable auxiliaries. When thus exhibited, the action of the Adrenalin is so mild that dilution is not necessary. The Inhalant may be sprayed into the nostril and repeated in four hours if required.

A writer in the Medical and Surgical Monitor for January, 1905, records several cases of chronic hay fever successfully treated with Adrenalin Inhalant.

Supplied in bottles of 1 fluid ounce.

ADRENALIN OINTMENT, a combination of 1 part of Adrenalin Chloride in 1000 parts of a bland oleaginous base, is preferred by some medical men as it prolongs local ischæmia.

Supplied in collapsible tubes with elongated tips to facilitate nasal medication.

Prior to using either of these preparations, crusts of mucus should be removed from the nasal passages by a spray of warm alkaline solution such as may be obtained by diluting ALKATHYMOL (P., D. & Co.) with three volumes of warm wacer, or by dissolving one Compressed Tablet NASAL (P., D. & Co., No. 34) in four ounces of tepid water.

The "GLASEPTIC" NEBULISER is the most suitable appliance for administering Adrenalin Chloride Solution or Adrenalin Inhalant. Being free from metallic fittings danger of contamination is avoided, and having no vulcanite parts it may be readily sterilised by boiling.

Upon request we shall be pleased to send to any medical man a pamphlet descriptive of many of the almost innumerable therapeutic applications of Adrenalin.

PARKE, DAVIS & Co., London.

270 mg

# Phosphorus Metabolism. Sanatogen Period. After Period. Period.

#### 4-9 day, 440 mg. Phosphorus Retention pro die.

# Sanatogen

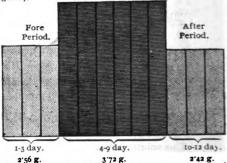

The virtue of Sanatogen is semething more than the sum of the action of its two component parts (Casein + Glycero - phospheric acid). Both these substances are of well-tried value, but in Sanatogen they are so blended and chemically combined as to constitute a new compound with properties exactly adapted to the wants of the human organism, and with quite specific therapeutic qualities.

A contribution to the study of the action of Sanatogen has been made by an English authority who conducted a series of investigations into its metabolism. They were submitted to the International Medical Congress at Lisbon in 1906, and published in the "Archives Internationales de Phar-

macodynamie et de Therapie," Vol. XVI. (See accompanying diagram).

#### Nitrogen Metabolism.

Sanatogen Period.

Nitrogen Retention pro die.

#### The conclusions of the author were as follows:-

 The retention of nitrogen by the system during the taking of Sanatogen is 48% more than on an ordinary diet.

10-12 day.

350 mg.

- (2) The retention of Phosphorus shows an increase of 63% during the administration of Sanatogen.
- (3) Practically the whole of the phosphorus in Sanatogen becomes assimilated.
- (4) The general diet as a whole is more perfectly utilised when Sanatogen is employed, that is to say tissue metabolism generally is stimulated.

Samples and Literature, Free to the Medical Profession, from The Sanatogen Co., 12, Chenies Street, London, W.C

# A Reliable Agent for all forms of Septic Mouth and Throat.

Used with the greatest success in Tonsillitis, Stomatitis, Thrush, etc.

His Excellency Professor von LEYDEN, Berlin University, writes:—

"I have used Formamint Tablets personally and have also prescribed them very frequently, and have been most satisfied with the results."

Professor Dr. Ed. KLEBS writes:-

"Formamint has done me excellent service in the disinfection of the mouth and throat, in Colds and in Influenza associated with laryngeal catarrh."

Samples and Literature free to the Medical Profession on application to A. WULFING & Co., 12, Chenies Street, London, W.C.

The above illustration shows an Agar Plate, the two halves of which were treated with Normal and Formamint Saliva respectively. Both were then inoculated with a typhoid culture. The right half, containing Normal Saliva, developed a virulent growth of the Colonies, whereas on the left half, containing Formamint Saliva, only scratches of the inoculation Spatula are visible. Such is the protection afforded by Formamint against all infectious diseases which effect their entry through the mouth.

#### An Efficient Prophylactic against Infectious Diseases,

such as Scarlet Fever, Diphtheria, Measles, etc.

"THE PRACTITIONER," December, 1907, vide Article on "An Analysis of 832 Cases of Scarlet Fever":—

"I regard these lozenges or tablets as a good prophylactic also against sore throat. I have never had a sore throat myself since I began to use them, although I periodically suffered before, and I always recommend their use to the nurses in the scarlet fever wards."

Beware of inefficient substitutes, which, not being chemical combinations, like Formamint, cannot act in the same manner. Insist on "Formamint Wulling."

# Formamint

#### NOTES AND COMMENTS.

Cosmopolitan Quackery.

THE existence of quackery in all nations of the world, whether civilised or otherwise, points to some common defect in the intellectual armour of mankind. Viewed

in the light of common-sense criticism and reduced to its first principles, there is nothing more ridiculous in the fantastic dress and capers of the North American "medicine man" than of the faith-healer of fashionable New York or London, who lays on his hands and prays over an unfortunate victim dying perchance of pneumonia or appendicitis. There is more excuse for the savage, however, inasmuch as he has probably no sounder system of scientific healing available than his own incantations. In London there have been for generations past one or two notorious bone-setting quacks, who have successfully defied the storms of time and amassed fortunes in comfortable security. In Paris their homologue is the famous Jacob the Zouave, who served in the Crimean war, and is a famous trombone player. For at least fifty years he has followed the lucrative calling of a faith-healer. He has been prosecuted again and again for practising medicine illegally, but without the slightest effect. The latest experience of the Courts appears to have placed him finally on a pinnacle of safety whence he may laugh at the enemy. A prosecution was undertaken against him by the Association of Physicians of the Department of the Seine, but the Court decided, as usual, in favour of Jacob. They held that a man who wore a long white gown, and who claimed to be in communication with spiritual agencies whom he could invoke at will, and who shook hands with his patients, could not be regarded as practising medicine. It would be interesting to get a definition from that particular Court of illegal medical practice. Meanwhile, we have our own Jacobs and our own Courts of special leniency towards gentlemen of his kidney.

Physician.

It is is seldom given the whole world The Sultan's to rejoice together over the degradation of a single person, but it is safe to say that every civilised being, not pecuniarily interested in the Court of

Abdul Hamid, has been relieved and delighted by the downfall of that blood-stained potentate. Even the ladies of his harem seem to have taken separation from their lord and master with great philosophy, and let it be hoped they may find such reward as Turkey has to offer for premature divorce. But we can understand that the revolution will not be contemplated with unalloyed satisfaction by Dr. Bier, the ex-Sultan's German physician, who was attached to his employer's Court at the handsome remuneration of £6,000 a year. Indeed, he is already

reported to be about to sue the Sultan's legal successor for damages for breach of contract, and perhaps, in commemoration of the new order of things, he will be awarded a decent solatium. To his professional confrères in this country, however, it will probably be felt that as a member of the profession he has had ample opportunity of providing for a rainy day out of the salary of a Lord Justice, when the highest official posts open to medical men in this country only carry a quarter of his salary, and the medical attendants of Royalty are reputed to be paid in hundreds which bear a very small proportion to Dr. Bier's thousands. At the moment we can only think Dr. Bier rather lucky, in a country like Turkey, to have escaped the revolution with only the loss of his position; if the Young Turks had followed the precedents of previous revolutionaries in their country, he would probably have lost his head also.

Death Certification.

THE medical profession is unanimous about the necessity of revising the present methods of death certifica-Certification: tion; perhaps more unanimous on that than any other subject, and we are glad to see the matter brought forward in

public on every good occasion. Nevertheless, it seems unfortunate that the occurrences at Wolverhampton, much trumpeted in the papers last week, was gravely made the subject of a question in the House of Commons. The incident in question consisted in the fact that a woman suffering from tuberculosis of the lungs and cerebral hæmorrhage died, and the husband applied to the medical attendant in due course for a death certificate, which was duly given. A nurse and some other women subsequently suspected that life was not extinct, and, placing a mirror in front of the dead woman's lips, and perhaps all examining it with rapid breathing, found a condensation of moisture on it. Neighbours were promptly informed and much excitement produced, so that the coroner decided eventually to hold an inquest. The jury found the prosaic verdict that the woman died at the date and time certified by the doctor. Now, we cannot help feeling that this was a most unfortunate case on which to demand that the system of death certification should be revised, for there seems to have been no really trustworthy evidence that the certificate was not properly granted and perfectly in order. At times of death and grave emergency many people lose their judgment, and nearly all the stories that are reported in newspapers and elsewhere of people being alive when they are supposed to be dead are found, on investigation, to consist of merely unsubstantial substance of which dreams are composed.

Medical Man to refer to the prosecution of Dr. and Town Councillor. Council of that city on the ground of having failed "forthwith" to

notify a case of scarlet fever occurring in his prac-We said at that time that the prosecution seemed to us so extraordinary and so much opposed to all public interests that we suspected that there must be some particular reason behind it all. En passant we may remark that Dr. Dickinson was acquitted by the magistrates on that occasion, and we hope and believe that every medical man accused under similar circumstances certainly always will be. The sequel to this action took place at Hereford Assizes last week, when Dr. Dickinson brought an action for slander against one of the town councillors for a statement made in the course of a speech at the council in October last in connection with the case, and in consequence of which his practice had suffered. Although the councillor, through his solicitor, had apologised, and had also apologised in public at a council meeting, the jury awarded Dr. Dickinson £ 100 damages. This is an excellent result, and we congratulate Dr. Dickinson on having vindicated himself. It is not always that medical men have the determination to go through with an action of this sort in which the worry and risk are so great, but we hope his example will encourage others not to take meekly slanderous statements such as persons in positions of authority like to fling at them. The result of this action will, we trust, be a salutary lesson to people with glib tongues who take advantage of the intricacies of medical practice to abuse medical men who are doing their best to combat the difficulties confronting them.

Vis a Tergo. A good deal has been said of late with regard to the free way some medical men give certificates of disability to members of clubs and friendly societies, and we confess

that we quite understand the difficulty which presents itself to doctors placed in the position in which such gentlemen find themselves. To refuse a certificate entails a careful examination to prevent possibility of error, taking up a far longer time than the club salary is sufficient to reimburse the examiner for, and in the democratically-constituted associations in which the doctor holds his appointment by annual election, to refuse certificates is one of the safest ways of ensuring loss of the appointment. In fact, the doctor is looked upon as a servant of the members who is bound to fulfill their wishes, and not as an independent official to act according to his own judgment. A medical man was summoned for assault last week at Sunderland by a member of a club to which he was medical officer, the allegation being that the member called to ask him to sign two certificates, and that the doctor had (literally) kicked him out of the house. The medical man's defence was that he constantly had to refuse to sign certificates for this man, and had told him not to come to the house again, having two months before told the lodge that the man was well. After some discussion a conference was arranged by the chairman and the summons withdrawn—perhaps the happiest solution of the problem. Reading between the lines, we gather that apparently a technical assault had been committed on a person who deserved sound chastisement, and though one cannot formally approve of the illegality, we think that there would be a great deal less "sponging" if poetic justice could be summarily executed on the weary Willies and tired. Tims who like lodge money better than that they earn with their labour.

#### LEADING ARTICLES.

### ENTERIC FEVER AS A DISAPPEARING MALADY.

ONE of the most striking facts in modern sanitary science is the rapid and more or less complete disappearance of certain zymotic maladies from the United Kingdom. There is no need to elaborate that proposition in addressing the readers of a medical journal; it will suffice to take small-pox as a preventable disease that has nearly gone, and cholera as one that has been altogether banished. As fresh scientific facts accumulate with regard to the natural history of zymotics, there can be little doubt that one by one the process of extermination, beneficent beyond words for the human race, will be extended over the remaining diseases of that class, no matter how hopeless the problem may appear in our present stage of knowledge. regards enteric fever, its persistence, in spite of manifold advances in ætiology, treatment and prevention, has for many years presented a somewhat. disappointing problem to workers in public health. Recent researches, however, have placed in their hands more detailed methods of attacking the specific infection, which must ultimately yield to the outflanking tactics of progressive scientific warfare. Otherwise, the typhoid fever outbreaks mysterious origin that occur from time to time in centres of population where sanitary administrations are of the best possible kind would be more than disconcerting. The medical officer of health of a city that has been thus invaded on several occasions within recent years has issued a document containing on one side an invitation to hospital physicians and others dealing with enteric fever cases to keep a register of convalescents from that malady with a view of securing the attendance of such patients for a period of six months, in order to determine bacteriologically their actual condition as to infectivity. The other side of the document in question contains some clearly written instructions to the patients themselves, and it is suggested that a copy be handed to the latter on leaving hospital. This practical effort at the education of the public through the agency of the medical profession is clearly the outcome of recently-acquired knowledge as to the maintenance and distribution of typhoid fever by continuously-infective persons, who are now generally known as "chronic typhoid carriers." Dr. D. S. Davies, the author of the abovementioned circular, quotes the report of the official inquiry by Lieut.-Colonel D. Semple, M.D., and. Captain Grey, M.D., on enteric fever in India:-"The result of inquiry by the Indian Government," he remarks, "into the prevalence of typhoid fever in the British Army in India has been to confirm very definitely the importance of the 'carrier' cases, and the investigators confidently declare that the problem of typhoid fever prevention amongst the British troops in India consists in the detection and control of the 'carrier' cases, especially in regard to participation in food preparation." bearing of this principle upon the convalescent

enteric fever patients that are constantly being sent home from troops stationed in foreign parts affords much food for serious reflection. In any case, it is obvious that the public should be informed in plain language of the risks that are incurred from convalescent patients. They must be informed that the specific germ of typhoid fever may remain for an indefinite period, and cause relapses even many years after the first attack. The convalescent patient whose intestines retain the infective organism may thus become a continuous and unsuspected centre of infection and transmit the disease far and near. Imagine the possible consequences with a patient of this kind at work in a dairy or on a dairy farm, with the manifold opportunities that must necessarily occur for the contamination of so sensitive a culture medium as milk. Dr. Davies has aptly summed up the position in this respect with the following full and suggestive list :- "Cooks, male or female, dairymen or dairywomen, milk vendors, greengrocers, butchers, fishmongers, provision dealers, workers in cocoa, chololate or confectionery, waiters and waitresses, and the mother who prepares food for the family, form a class of convalescents in which the opportunity of transmission of the disease are very frequent." The provisional rules which he appends are so excellent that we make no apology for reproducing them, in the hope that other medical officers of health may follow this example. They are as follows:—"(1) The hands and nails should be thoroughly washed, first in disinfectant solution, then in soap and water, and well rinsed before touching any foodstuffs, especially milk. (2) After the bowels are opened or the bladder is emptied the hands and nails should be at once disinfected and washed. (3) Strong disinfecting solution should be poured over the stools, &c., before the plug of the water-closet is used or the lid of the dry closet is shut down. (4) When the motions are loose the risk of infection is increased and additional care should be taken. (5) The convalescent should periodically visit the medical attendant, so that the blood, &c., may be tested, and measures may be taken to control the action of the germs. As there is generally no need to deal with the drains, or to disinfect rooms or houses for these special cases, no upset of the domestic arrangements is necessary. (6) In the household where a patient is convalescing from typhoid fever the additional precautions of boiling all the milk or water used for drinking or in the preparation of food should be undertaken, and uncooked foods should be avoided." It is only by the general observance of precautions of this kind that we may hope ultimately to banish from our midst a scourge that has afflicted society from time immemorial.

#### CURRENT TOPICS.

#### Lying Medicines.

An effective method of dealing with the quack scourge is, we understand, being adopted in America by the Food and Drug Department of the Department of Agriculture; at any rate, it has been already put in force in one State. A patent medi-

cine described as "curing croup, whooping-cough, diphtheria, all throat troubles and catarrhal disorders" was taken in hand by the inspectors of the department. Forty-one boxes of this preparation were seized and subjected to analysis, and the report of the medical staff of the board was that it would not cure the diseases mentioned. Consequently the Department ordered the lot to be destroyed, because "it was evident that the preparation was misbranded . . . . for the reason that the statement given on the label that it would cure the diseases mentioned was unwarranted and untrue, and therefore false, misleading and deceptive." This incident raises the question as to whether the sanitary authorities of this country have not already power to prosecute in the case of lying statements made with regard to patent medicines in this country. As administrators of the Food and Drugs Act, could they not prosecute offenders who claim on their labels all sorts of magic powers for their wares, on the ground that the stuff supplied was not of the "quality, nature and substance demanded by the purchaser "? We think that if a man demands a cure for kidney disease and is supplied with a solution of half a grain of potassium nitrate with a little sugar in an ounce of water, a prosecution clearly lies. Will any of our sanitary authorities have the courage to bring a test case?

# The Annual Election at the Royal College of Surgeons, England.

THE election to the vacancies on the Council of the Royal College of Surgeons, in July next, will be of more than usual interest, owing partly to the personnel of the candidates who are competing, and partly to the decision of the retiring councillors each to seek re-election. Thus for the three vacancies created there is, in a sense, no actual vacancy, inasmuch as the rule generally obtains that those councillors, retiring by rotation, who seek re-election are accorded again the support of the majority of the Fellows. The full list of the candidates is as follows: -- Mr. Clement Lucas (1871), Sir Watson Cheyne (1875), and Mr. Mayo Robson (1879)—these are the retiring councillors; Mr. Harrison Cripps (1875), Mr. C. A. Ballance (1882), Mr. Bland-Sutton (1884), Mr. Walter Jessop (1884)—of these Mr. Cripps has already filled a substitute vacancy upon the Council, and last year was a candidate for re-election, but failed to be successful. He is the senior surgeon at St. Bartholomew's Hospital. would be invidious to particularise the claims of these candidates for the coveted honour which they seek, each of whom is well known as a prominent member of the staff of the medical school to which he belongs. In days, however, gone by, the success of a candidate depended, not so much upon his personal position as upon the views which he held in respect to so-called "college politics." The elections were then interesting, and even exciting, the poll taking place under conditions which, in a minor degree, resembled that of a contested parliamentary constituency, the opposing parties being the Council and their friends on the one hand, and the reforming body of Fellows on the other. somewhat remarkable feature in relation to the latter body, known as the Association of Fellows,

was that the majority of its most active supporters were included among the older Fellows of the College, and so it has come about that out of nearly twenty members comprising the former committee of the Association only about four are now alive. Sic transit gloria mundi. College politics, then, for the present, as far as the Fellows are concerned, having become a negligible quantity in respect to the College election, the success of a candidate may be said to be determined, almost entirely, by his personal popularity. But even this will not help him much unless he worries his friends and all who have the power to help him, to accord him their active support. As a matter of fact, success at the poll, even on the part of a favoured candidate, demands the expenditure of much time and trouble, and especially so will this be the case on the present occasion, owing to the somewhat unusual circumstances in which the election is taking place.

#### The German Birth-Rate

THE decrease in the birth-rate in the United Kingdom has not hitherto been attended by a shrinking population, as in the case of France. In foretelling disaster in our own country, pessimists have persistently pointed to Prussia as the one country that, under all conditions, has continued to advance in its birth-rate. Of late, however, a change has come o'er the spirit of the scene, and Prussia appears to be falling under the operation of the laws or altered conditions that have reduced the output of population in so many other countries. We find, for instance, that the total of Prussian births for the year 1907 was about eleven thousand under that for 1906. In 1904 the proportion of births per 1,000 of population was rather more than thirty-five; in 1905 is was thirty-three and threequarters, in 1906 it was thirty-four, and in 1907 thirty-three and a quarter. In Berlin the percentage of births to population is about half what it was thirty years ago, and the country in order to maintain its rate of increase must obviously depend on immigration from other parts of the country. In some of the most prolific parts of Prussia, such as Westphalia, the population has of late become stationary. On the whole, it looks as if Prussia has passed the top of the curve of increase and is now following the down grade shared in greater or less degree by most Continental nations.

# The Irish Medical Benevolent Fund Society.

An interesting letter appears in the daily press from the pen of Dr. H. G. Molony, of County Limerick, with regard to a proposal which he submitted at last year's meeting of the Irish Medical Benevolent Fund Society. Dr. Molony's proposal is, that in view of its deficient funds, the Society should restrict its charity to former subscribers and their families. Dr. Molony's reasons for this proposal, which is at variance with the present course pursued by the Society, are that, first, only a small minority of the profession subscribe to the charity; secondly, that the greater majority of the recipients of its bounty are the very men who have not been subscribers; thirdly, that the annual income is so small that only very small grants can be given.

The objection usually brought forward to Dr. Molony's proposal was voiced at the last meeting by Mr. Lentaigne, President of the Royal College of Surgeons in Ireland, who said that its effect would be to change the Society from a charity into an assurance company. To this Dr. Molony replied-and we think very rightly-that were his proposal adopted, even if a man subscribed one hundred pounds a year to the Society, he would never get a penny from it unless he or his family became destitute. In an assurance company, on the other hand he would get a return on his subscriptions even if he were a millionaire. Molony also instanced the case of one of the Press charities which restricts its grants to former subscribers who become destitute. We can quite understand the reluctance of the Society to change its present and most altruistic mode of conducting its affairs, but the question really is not what has been best and most praiseworthy in the past, but rather what will make the Society most able to carry out its beneficent work in the future. From this point of view we think that Dr. Molony's proposal is well worthy of the careful consideration which it is certain to receive, and that, if adopted, the Society would find that it would result in more subscribers, and hence in a larger income.

# The London and Counties Medical Protection Society.

THE annual report of the London and Counties Medical Protection Society registers a period of steady advance in numbers, in prosperity and in usefulness. The applications to the Society during the year numbered 557, and of these it is noteworthy that 133 were from members practising as dentists. The surplus of income on the year's income is £236 15s. 10d., a sum less than in the two preceding years, owing apparently to increased law expenses. In spite of that fact, however, the balance to credit of the Society stands at some £3,800, as against £3,500 in 1907, and £3,100 in 1906. The Reserve Fund of the Society stands at £4,298 8s. 4d., so that any medical man who contemplates becoming a member may rest assured as to its substantial financial position. One extremely encouraging feature in that respect is the large amount of donations which go to swell the reserve. The cases undertaken by the Society during 1908 were of the usual kind, and included the settlement of various disputes arising out of partnerships and the sale of practices. Some useful work has been done in bringing pressure to bear upon local authorities administering the Midwives Act. Sir Jonathan Hutchinson, F.R.S., still presides over a distinguished body of vice-presidents and council, with the able assistance of Dr. Hugh Woods and Dr. A. G. R. Foulerton as secretaries.

## The Medical Curriculum.

The Report of the Education Committee of the General Medical Council, which was presented to the Council at its recent session, and postponed for discussion to November, will be received with disappointment by those who look for drastic changes in the present curriculum. The Report is conservative in the extreme, and practically proposes to leave things as they are. One important proposal referred to the Committee was that the "preliminary

sciences" should be transferred from the curriculum to a stage preliminary to the commencement of medical study. On this the Committee remark that "all are agreed that the knowledge to be derived from the study of the preliminary sciences is to be considered an essential part of the equipment of a medical man." In this broad statement we can hardly agree. There is no doubt that the study is of high educational value, but the actual knowledge gained by an ordinary medical student of, let us say, biology, is hardly so considerable in amount as to be of any service in a medical man's equipment, much less an essential part thereof. As for its educational value, if physiology and anatomy are properly taught, pure biology is unnecessary. On one point we congratulate the Committee—the refusal to prolong the course from five to six years. At the same time, while definitely deciding that five years should be the length of the course, they suggest such reservation of time for clinical work, apart from the earlier studies, as is likely to swell the course beyond the allotted time. We hope that before the Council makes a final decision in the matter, the entire subject will be carefully considered by the members.

Registration of Nurses
When a deputation waited on the Prime Minister a few weeks ago to press on his attention the question of the registration of nurses, he declared his inability to move until there should be signs of greater unanimity on the subject. The manner in which this answer has been received in Ireland and Scotland respectively shows how far we are from the desired unanimity. In Ireland a mass meeting of nurses, with a live Member of Parliament on the platform, has been held to protest against the procrastination of the Premier. In Scotland, on the other hand, the Executive Committee of the Association for the Registration of Nurses in Scotland has passed a resolution congratulating Mr. Asquith on the stand he made. The real reason of the Scottish opposition is that in Scotland they wish to have their own system of registration independent, at any rate to some extent, of the rest of the Kingdom. In Ireland, on the other hand, they want a uniform system of registration for the three countries, believing that if different registering authorities were appointed, nurses trained and registered in Ireland would be placed at a disadvantage if seeking work in England. For our own part, while admitting the advantages to be gained from a State register in the power of distinguishing nurses of some standing from impostors, we see many objections to the institution of a new order of medical practitioners, possessed of a certain quasi-recognition. The working of the Midwives Act is a warning against any further legislation of a similar nature. We therefore cannot pretend to regret Mr. Asquith's non-committal attitude.

### PERSONAL.

MR. LEONARD A. BIDWELL, F.R.C.S., Surgeon to the West London Hospital, has been elected President of the Chelsea Clinical Society for the ensuing year.

A QUESTION has arisen at Brighton regarding the remuneration of Dr. A. Griffith as Medical Officer of Health for Hove. The present salary is £450 per annum. This, it has been proposed, should be raised but there is consolidated to the salary in the salary in the salary is the salary in the salary in the salary in the salary is the salary in the salary in the salary in the salary in the salary is the salary in the salar to £500, but there is opposition in the Council.

THE Harben Gold Medal of the Royal Institute of Public Health has been awarded by the Council to his Excellency Professor E. von Behring, M.D., of Marburg.

BREVET LIEUT.-COLONEL W. B. LEISHMAN, M.B., M.A.M.C., Professor of Pathology in the Royal Army Medical College, has been appointed by the Council of the Royal Institute of Public Health Harben Lecturer for the year 1910.

DR. J. LUCAS-CHAMPIONNIERE, the famous French surgeon, who is President of the International Congress of Surgeons, visited Cardiff on June 4th, and delivered a lecture to the Medical Society of the city in the oftenness and was the principal guest at the in the afternoon, and was the principal guest at the Society's dinner, whilst during the evening he made a presentation to Mr. Lynn Thomas and Dr. Skyrme on behalf of the medical profession generally.

A DINNER was given in the Liverpool University Club on Monday to the Tropical School of Medicine experts, ten of whom have returned from expeditions this year. Among the latter were Professor Ronald Ross (malaria in India and Mauritius), Professor Sir Rubert Royce and Dr. Wollersham Thomas (yellow fever in the West Indies and Brazil respectively), Dr. J. O. W. Barratt and Dr. Warrington Yorke (blackwater fever in Central Africa), Dr. A. Kinghorn and Mr. R. E. Montgomery (sleeping sickness in Rhodesia), and Dr. W. T. Prout and Dr. A. H. Hanley (malarial fever in

A FINE monument has been erected by the admirers of the late Dr. J. N. Patterson, the oldest medical practitioner in Earlestown. It was publicly unveiled by Colonel J. D. Murray, V.D., of Wigan, in the Cemetery at Newton-le-Willows, last week.

MRS. ANNIE JANE HOLBORN, of Campden Hill, who died in April last, amongst many other charitable bequests, left £5,000 to St. Bartholomew's Hospital.

THE late Mr. Claudius Galen Wheelhouse, F.R.C.S., D.Sc., LL.D. whose death at the age of eighty-two lately took place, left estate valued at £18,590 gross, with net personalty £17,481.

THE summer dinner of the West African Medical Staff will take place on Monday, June 21st, at the New Gaiety Rsetaurant, Strand, London, W. Members of the staff who desire to be present are requested to communicate immediately with Dr. Prout, C.M.G. 78 Rodney Street, Liverpool.

LAST week the Convocation of the University of Oxford approved two decrees accepting from Dr. Theodore Williams £2,500 to establish two scholarships in physiology, and £2,500 to establish two scholarships in human anatomy. The Vice-Chancellor proposed the decrees and expressed the gratitude of the University to Dr. Williams for his liberal bene-

SIR FELIX SEMON, K.C.V.O., Physician Extra-ordinary to the King, is retiring from practice—and the occasion will be marked by a complimentary banquet to be given him by his professional and other friends, on Friday, July 2nd, at the Whitehall Rooms, Hotel Metropole. The organisers of the banquet are anxious to found a lectureship or scholarship in his name to be a record of his scientific work as one of the founders of the British School of Laryngology of the founders of the British School of Laryngology. Mr. Henry T. Butlin, F.R.C.S., D.C.L., will preside at the dinner, and all communications with regard to the Testimonial Fund or application for seats at the banquet should be addressed to the hon. secretaries: Alfred Mond, Esq., M.P., 35 Lowndes Square, S.W.; P. Watson Williams, Esq., M.D., 4 Clifton Park, Bristol; H. J. Davis, Esq., 8 Portman Street, London, · E \_\_

# A CLINICAL LECTURE

ON THE

## TREATMENT OF BRONCHO-PNEUMONIA. (a)

By EDMUND CAUTLEY, M.D.Cantab., F.R.C.P.Lond.,

Physician to the Belgrave Hospital for Children and to the Metropolitan Hospital.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

GENTLEMEN,-Broncho-pneumonia is one of the commonest diseases of infancy. About half the cases occur in the first year of life, a third in the second year, and one-tenth in the third year; leaving only about one-fifteenth for the remainder of life. This distribution is important from the point of view of prophylaxis. Several of the cases are primary, but quite two-thirds of them are secondary. You might divide them up into groups according to their severity, their anatomical distribution, or their main characteristics. Thus, one class of case is fatal in from 12 to 36 hours; a less severe type lasts for a period varying between 6 and 10 days; a third type is prolonged for 3 or 4 weeks, and occasionally for 6 or 8 weeks; a fourth type is cachectic in character, with little or no fever, and very often no evidence during life. On anatomical grounds one speaks of a capillary bronchitis, in which no physical signs of consolidation are found, though you will be practically certain to find small patches after death; or there is a lobular pneumonia, in which there are definite small patches of bronchial breathing; or these lobular patches are aggregated into larger masses involving the whole lobe, or nearly so. Any one of these conditions may be either unilateral or bilateral. You can also divide them, according to their main features, into those in which the obstructive symptoms predominate, others in which the cardiac symptoms are most pronounced, a third type in which the nervous symptoms are very characteristic, a fourth type in which there is asthenia, and a fifth characterised by profound toxæmia.

In speaking of the treatment of this disease I can only speak generally. I must leave you to judge what is appropriate for the particular case.

First, with regard to prophylaxis. The most important consideration is that the child should be put under the best conditions of life from the day it is born. In other words, it must be brought up on the breast in preference to the bottle; must be suitably clad, not exposed about the legs, buttocks and arms, as delicate children often are; and it must be brought up under suitable conditions of hygiene as regards ventilation and bathing. Furthermore, it is of the utmost importance to guard babies up to the fourth or fifth year of life, from those infectious diseases to which broncho-pneumonia is so commonly secondary, namely, by keeping them from exposure to the infection of measles, whooping-cough and influenza. You must also attend to any naso-pharyngeal catarrh which may be present, and give great attention to the treatment of even mild bronchitis and to all forms of gastrointestinal trouble, for many attacks are a terminal event in cases of ileo-colitis.

With regard to nursing, it is important that when a child is seized with an attack of broncho-pneumonia the room should be kept at an appropriate temperature, viz., 60° to 65°, or in the case of a weakly or premature infant, 65° to 70°. The open-air treatment is extremely useful, especially in secondary cases, where the attack is not due to exposure to cold. By this I mean the child should have a free supply of pure air, though not necessarily every kind of atmosphere. Certainly it does not mean reckless exposure to raw, damp, or foggy air. The child should be protected also from strong winds. You can

provide a sufficient supply of pure air in the room by keeping the windows open, and warming the atmosphere by fires, protecting the child from draughts by screens. The child should wear a flannel nightdress and cotton-wool jacket, unless the temperature dress and cotton-wool jacker, unless the temperature is very high. In a bad case you will see the effects of open-air treatment very quickly; the child becomes less restless and irritable, the face is less flushed, the lips less cyanosed; both pulse and respiration rates fall, the appetite improves, the child sleeps better, and the strength is well maintained. I know of only two definite contra-indications to a large supply of open-air for this complaint, namely, convulsions and laryngitis. In these cases you have to exercise even greater precautions than those I have mentioned. In all cases of broncho-pneumonia the diet is the next factor of importance. The disease is a very depressing one, especially in toxemic cases and those which are secondary to infectious disease, and there is marked liability to intestinal disorder, notably tympanites. So you must give a diet which is nutritious and readily digestible. Breast feeding is best, and if the mother is nursing the child, it must be continued. Failing that, you must rely upon milk, suitably diluted, peptonised if the child does not digest it, and sweetened with cane sugar, or with lactose if there is diarrhoea or tympanites. It can be further strengthened by the addition of protein, in the shape, for instance, of plasmon or other dried casein preparation. You can also give veal or chicken broth, and plenty of water. In the early and acute stages you had better be content with regular small feeds, composed of the foods I have mentioned. Such children are very constantly over-fed, and suffer in consequence; for if they get gastric or intestinal distension, the diaphragm is apt to be pressed up and the breathing and action of the heart to be interfered with. At the very onset it is justifiable in some cases to give an emetic, but on the whole, my experience of emetics is not very satisfactory. They are only justifiable in the case of robust infants who are suffering from great mechanical obstruction on account of the excessive secretion into the bronchial tubes. But emetics are very depressing. If you give one, I think the best is powder of ipecacuanha, 5 to 15 grains, according to the age of the child, repeating it in ten minutes, and again if necessary; and giving a liberal supply of water. It is better, on the whole, than tartrate of antimony,

of which one-sixth to one-third of a grain is the cose. At the onset of an acute attack with fever, much good can be done by means of hydrotherapeutic measures. A bath at a temperature of 90° to 95° reduced down to 30° or even 75°, given for a period of five or six minutes, may sometimes cut short an attack. In giving it, sit the child in the water, support its back with the hand, and do not let the water rise above the level of the lower ribs. Sponge it freely all over, then wrap it up in a warm blanket, and put it back to bed. It is advisable to give some stimulant before such a bath. A bath at a temperature of 90° to 95° may be given night and morning, or as often as every three hours, if there is a temperature above 102°. At the onset of an attack, especially in the congestive cases, poultices may be very useful. There is too great a tendency nowadays to discard poultices and to speak of them with contempt, choosing bot fomentations in preference. But the latter are more difficult to apply successfully, more liable to make

<sup>(</sup>a) Delivered at the Polyclinic, Chenics Street, London, W.C., on Monday, May 3rd, 1909.

the bed wet, and to chill the child subsequently. You can use a poultice of linseed, linseed and mustard (one part of mustard to eight of linseed), bread, or bran. But see that the poultice is sufficiently large for the child to lie in, and that the poultice does not extend on to the front of the chest or abdomen. it does, it will interfere with breathing. Change the poultices frequently, and do not allow them to stay on until cold. Usually it is good to start with a poultice every twenty minutes for a couple of hours, and then put on a cotton-wool jacket. See that the poultice is applied at the proper temperature. It is not uncommon among the lower classes to apply fomentations and poultices too hot, causing much pain, blistering of the delicate skin, and severe scarring afterwards. No doubt pain acts as a counter-irritant, but it is rather a cruel kind. It is better to rely upon some simple kind, such as camphorated oil, turpentine liniment, mustard leaf, or-a very useful preparation which is not widely enough known—electra cloth. This is a cloth which has been impregnated with Chillie paste, and is damped and placed on. The Chillie paste, and is damped and placed on. degree of irritation varies with the degree of dampness, and the duration of the application. If you want stronger measures, use a mustard pack or a hot mustard bath.

With regard to drugs, you can sometimes do good in the early stages by the administration of belladonna, in doses of 4 or 5 minims of the tincture, or ‡ grain of the extract every three or four hours, according to the age of the child and the severity of the case. Belladonna is given for three reasons: To reduce the bronchial spasm, as a cardiac and respiratory stimulant, and to diminish the amount of secretion in the bronchial tubes. If it is going to produce any good result it will do so in a few hours, say twelve. If it does not cause a definite result in twenty-four hours, I think it should be discontinued.

It is advisable to combine the belladonna with diuretics and diaphoretics. If you can induce the skin to act freely, you will relieve the congestion of the lungs, and also the toxemia, which is sometimes a very pronounced feature. Occasionally one meets with cases which have been treated with aconite, the doses being usually 1 to 1 minim, combined with a little alcohol, and given every hour for twelve to twenty-four hours. I am not very much in favour of it, for aconite is a powerful cardiac depressant, and in broncho-pneumonia I think it is advisable to avoid such depressant drugs as aconite, ipecacuanha, antimony, and coal-tar products; or, if used at all, they should be in only robust infants, and with very great care. Tincture of veratria is also used in small doses every two hours. It is difficult to make certain whether drug treatment has anything to do with the result, as many cases subside very quickly without any special treatment, whereas others will go on and become more severe, no matter what measures you adopt. Another drug which is very useful in early cases and in all stages is carbonate of ammonia, which I do not think is given sufficiently freely. When one is called in to see such a patient, which is generally not until twelve to twenty-four hours have elapsed from the onset, a very good combination to give is I grain of carbonate of ammonia, a little iodide of potassium or ammonium chloride, tincture of nux vomica, syrup of tolu, and chloroform water; the doses being proportioned to the age of the child. Usually for a child under one year of age, you will find that 1 to 4 grain of carbonate of ammonia is given. But I do not hesitate to give a grain, even to a child six months of age, and I have not seen it cause any ill effects. Later on, if you want to increase the secretion and render it less tenacious, you must rely on the carbonates and iodides of sodium and potassium, ammonium chloride, and benzoate of soda. And in addition, you can give stimulating expectorants, more especially tincture of squill and tincture of The first of these is a most valuable drug, for not only is it an expectorant, but a powerful cardiac tonic, almost as good as digitalis. Vinum ipecac. and vinum antimonialis have, in my experience, very

little effect unless they are given in depressant doses, and depression ought to be avoided. If you use any coal-tar products, let it be phenacetin, in doses of 1 to 3 grains every two to four hours, according to the age. I use it especially in nervous cases in which there is very high fever. It relieves those symptoms, and also headache if present, though the latter is not common, especially where the fontanelle is open. Antipyrin may be used, but antifebrin is too powerful a drug. Quinine should not be given by the mouth, as it is liable to upset the digestion. If you give it at all, give it by the rectum, in doses up to 5 grains, dissolved in water. Keep the bowels acting regularly but without setting up diarrhea, and for this it is best to rely on small frequent doses of calomel or grey powder. Strong purges are apt to set up fatal ileocolitis, and should be avoided. And, for fear of upsetting the intestinal tract, avoid giving cough mixtures, especially those made up with syrup. One is constantly asked in these cases whether one should make use of the bronchitis kettle. Under some circumstances, it is beneficial, but, under others, injurious. If the atmospheric air is very dry, and the cough hard and dry, then the steam does good by moistening the air and loosening the secretions. If, on the other hand, the atmosphere is moist and cold, and the secretion in the lungs is profuse, then I think that inhalations from the steam kettle are distinctly injurious. If you use a steam kettle, it is generally advisable to put the child in what is called a half-tent; if you use a whole tent you will keep out too much fresh air. Remember the vapour from the steam kettle is apt to condense and become cold when you have the windows open, and then the child inhales nasty cold, damp vapour. Inhalations do good undoubtedly, but it is simpler to give inhalations of turpentine, eucalyptus, creosote, or thymol, by sprinkling the drug on a sponge, lint, or flannel, and holding it in front of the child's nose and mouth for five or ten minutes every two hours. I think much of the benefit of turpentine liniment is derived from the vapour inhaled. An inhalation may increase the secretion, or it may decrease it, according to the kind used. With regard to special complications, I must mention first of all, tympanites and severe diarrhea, for they are the commonest complications, and they are dangerous ones. In the treatment of tympanites, it is advisable to starve the child entirely, unless extremely debilitated, giving nothing but water for a time. If the mischief is gastric, wash the stomach out with a solution of bicarbonate of soda, 4 grains to the ounce of water. If the tympanites is due to intestinal distension, the passage of a rectal tube, or, still better, an enema of asafetida and water, will lead to the evacuation of the wind. You may also give fairly large doses of nux vomica, or liquor strychninæ, in order to stimulate peristalsis. Severe diarrhea is treated on dietetic lines, and generally that is sufficient. Occasionally, it is necessary to give small doses of tincture of opium, in order to check the excessive peristalsis. Of course, this may make the child drowsy, and increase the pulmonary congestion by interfering with efficient respiration, so it is a matter of grave responsibility to prescribe opium for these patients.

In the treatment of very high fever, you can apply cold compresses to the chest every two hours, or use the cold or tepid bath, applying cold to the head at the same time. For the nervous symptoms, which may or may not be associated with high temperature, you must adopt cold or heat—cold if there is a high temperature, heat if the temperature is subnormal. A hot bath, with moderate fever, affords more relief than a cold bath does. A cold bath should not be given if the temperature is below 102° F. In the case of sudden collapse, which may arise from cardiac failure, either due to rapid distension of the heart, from toxæmia, or mechanical obstruction in the lungs, or the sudden collapse that is due to atelectasis, you have to use very free stimulation. There is nothing equivalent, in the worst cases, to the mustard bath at a temperature of 85°, or a mustard pack. Usually

these mustard baths are given at too high a temperature, namely, at 100°, but the effect of the mustard is reduced by temperatures above 85°. In giving a mustard bath, the child is immersed up to the neck, the head being free, and the neck protected, so that the child does not inhale the mustard vapour. After the child is taken out of the mustard, it should be washed rapidly and well with water at a temperature of 90° to 95°, and wrapped in a warm blanket. In addition, give inhalations of oxygen, or of amyl nitrite; in all bad cases of broncho-pneumonia, you should have a cylinder of oxygen at hand. Then, too, you can give by the mouth stimulants very freely. Brandy is the best form, or you can use strychnine, nitro-glycerine, camphor, or caffein. If the case is definitely due to cardiac failure, large doses of carbonate of ammonia, sal volatile, ether, or nux vomica may be given; or you may give nitro-glycerine by mouth or subcutaneously, in doses of 1-500th of a grain. Strophanthus and digitalis are also useful; and very often they are given in the early stages to guard against this dilatation of the heart. If you give either of these drugs when the dilatation is fairly fully established, I think you will do more harm than good. If the dilatation of the right side of the heart is very definite, sufficient to cause dyspnæa and some cyanosis, before giving drugs such as digitalis and strophanthus, you ought to apply one to three leeches about the level of the right nipple. Leeching relieves the right side of the heart better than any other method it is possible to adopt. After you have brought about this relief, your drugs will be much more efficacious.

Where one has to deal more definitely with failure of respiration, you sometimes get good results from the injection of atropine, in doses of 1-1,000th to 1-500th of a grain, combined with strychnine in doses of 1-400th to 1-100th of a grain, and caffein, 1-10th of a grain. Such cases should also be encouraged to breathe deeply by inducing frequent crying and by alternate hot and cold douching of the chest.

Where there is much passive congestion at the bases of the lungs, dry cupping is of great use. This method of treatment is not used nearly sufficiently. A very great point in the nursing of these babies, and more especially in nursing wasted babies in hospital, is that they should not be allowed to lie, as they so often are, on their backs nearly all day long. That causes congestion at the bases, and increased difficulty of respiration. In hospitals, it is impossible for the nurses to nurse the babies as much as they can in private, but the nurse should prop the child up in a sitting posture occasionally, and place it first on one side and after a time on the other, and occasionally in the prone position.

In the convalescent stage you have to remember there is a great liability to recurrence and hence you have to adopt much the same hygienic precautions which you would in a case of incipient tuberculosis. Patients are likely, especially if their broncho-pneumonia was secondary to whooping-cough, to have a dilated right side of the heart, and will suffer in consequence from anæmia and shortness of breath. The dilatation may not be recovered from for several months. Some of them are left with a chronic cough, which is best treated with creosote or terebene preparations. The ordinary convalescent should be treated by cod-liver oil, iron preparations, arsenic, and small doses of quinine. If possible, choose for these patients a warm and dry climate, and in hot weather a high altitude.

But, remember, much of this treatment is often quite unnecessary, for mild cases of broncho-pneumonia, especially if primary, will recover under the simplest methods of feeding and nursing. In cases complicated by mechanical obstruction from excessive secretion in the lungs, you have to pay chief attention to relieving this congestion by means of drugs and counter-irritation to the chest. If the toxemic symptoms are pronounced, you have to rely upon alcohol and strychnine, and upon elimination. So

you have to treat every case according to its severity, and proportion your remedies according to the type of disease.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Prof. Leon Delmas, M.D., of the Faculty of Medicine of Paris. Subject: "The Treatment and Diet in Infantile Castro-Enteritis."

### ORIGINAL PAPERS.

# SOME RECENT RESEARCHES ON THE

# FUNCTION OF THE NON-AUDITORY EAR.

By R. H. WOODS, M.B., F.R.C.S.I., Surgeon for Throat, Nose and Ear to Sir Patrick Dun's Hospital, Dublin.

(Concluded from page 581.)

EWALD conducted experiments which demonstrate the fact that these eye movements have their reflex origin in the internal ear. He laid bare the right horizontal semi-circular canal of a pigeon, and made a small opening into the bony canal at some distance from the ampulla. This opening he plugged, so as to stop the flow of the endolymph in the membranous canal. He then made a second opening between the first one and the ampulla, and laid bare, but did not wound, the

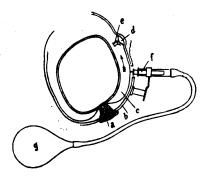

Fig. 6.—Diagram of Ewald's experiment (Bárány).

membranous canal. He then fixed a tiny piston worked by air-pressure from an elastic bag, so that when the bag was compressed, and the piston driven against the canal, the endolymph moved in the direction of the ampulla. He found that compression of the bag was followed by a slow movement of the bird's head and eyes to the left in the horizontal plane, while by relaxing the bag and drawing the piston away, a slow movement of the head and eyes in the opposite direction took place. The first movement corresponds to a right, and the second to a left, nystagmus. In the same way, by experimenting with the other canals, he was able to induce movements of the head and eyes in the plane of the canal with which he was dealing. He thus proved in a very elegant way the truth of Flourens' law. It should here be remarked that nystagmus in man differs in one important respect from that of animals. In man the nystagmus is purely ocular, while in animals the head partakes of the movement as well.

Considering the minuteness of the membranous canal, and the great friction of the endolymph against its walls, the amount by which the crista moves must be most minute, and in the same way the tug exerted on the maculæ by the inertia of the statoliths must be immeasurably small, but this need not prevent us from

admitting such stimuli to be adequate, when we consider how small a quantity of energy in the form of light or sound suffices to stimulate the retina or the cochlea.

Since every movement of the eyeball is a purely rotatory one, we must, for purposes of reference, speak of them as taking place in one of the three chief planes of the body, or some combination of them. But since the front of the eyeball is the part practically observed. we only speak of the movement as it affects, say, the cornea or iris. Thus nystagmus in the horizontal plane is called horizontal. Nystagmus in the sagittal plane is called vertical; while nystagmus in the coronal plane is called rotatory. In horizontal and vertical nystagmus the whole front of the eyeball moves in the same direction, and the nystagmus derives its name from the direction of the quick movement; but in rotatory nystagmus, while the upper part moves in one direction, the lower part moves in the opposite. The direction of rotatory nystagmus is said to be that of the quick movement of the upper part of the eyeball. Thus, if the quick movement is in the direction of the hands of a clock in the patient, he is said to have rotatory nystagmus to the left, and conversely.

We can produce experiments in man parallel to Ewald's by turning a patient in a rotating chair. If the body be rotated round a vertical axis with the head erect, the horizontal canal is the only one stimulated,

and pure horizontal nystagmus results.

In the same way rotation in the plane of any other canal will induce eye movements in its plane. A short consideration of the matter will show that the effect of rotation on the endolymph in any given canal will depend on the relation of the canal to the plane of rotation. When these planes coincide, the effect is a maximum, but as the plane of the canal gradually differs from the plane of rotation, the effect on the endolymph gets less and less, until, when their planes cut one another at 90, it becomes null.

The influence of rotation on each canal can be pre-

The influence of rotation on each canal can be predicted when we find out the angle at which the plane of rotation cuts that canal, and it will vary as the cosine of the angle. Now, since we have three canals, each at right angles to the others, every plane of rotation, no matter how situated, will have its corresponding combination of canal effect, and the effect for each plane will differ from that of every other plane, and will be represented by the formula—

E=f (cos.  $a+\cos$ .  $b+\cos$ . c), where a, b, and c are the angles made by the canal planes with the plane of rotation. By this mechanism the nystagmus evoked by rotation in any plane is always in that plane in other words, the plane of rotation of the head will always be the plane of nystagmus.

It may be useful to give a few examples to illustrate the effect of rotation in nystagmus. If when seated in a chair revolving to the right the head is erect, the nystagmus will be right horizontal. If the head showed forward at a right angle, so that the eyes look downwards at the centre of rotation, the resulting nystagmus will be purely right rotatory.

If the head is inclined to the right shoulder at an angle of 90°, and the patient is turned to the right, the clane of the nystagmus will be vertical with respect to the body. Intermediate positions give intermediate results. If the head be bent forwards at an angle of 45°, the nystagmus during right rotation will be partly

right horizontal and partly right rotatory.

There is one case where the movement is a little confusing on account of the nomenclature. During right rotation with the head erect we get, as we know, horizontal nystagmus in the same direction. If the head be bent back by 90°, so that the face looks upwards, we still get nystagmus in the direction of rotation, but since the absolute direction of the quick movement of the eyes is against the hands of a clock on the ceiling, it will be with the clock in the patient, and is by definition left rotatory nystagmus; in the same way, after right turning, we get right rotatory nystagmus. If a position between these two be chosen, say where the patient looks upward at an angle of 40°, we get during right rotation right horizontal and left rotatory nystagmus, while after right rotation we get left horizontal and right rotatory, and the horizontal element

will be accentuated by looking to the left, and the rotatory by looking to the right.

If a person has one labyrinth destroyed, it is found that, if he is rotated first in one direction and subsequently in the other, the duration of the after nystagmus evoked is different in the two cases.

Suppose the left labyrinth destroyed, and the patient is first rotated to the right, the cupula of the right horizontal canal is distorted towards the vestibule during rotation, and away from it when rotation is stopped. Conversely, after rotation to the left the distortion is towards the vestibule. Now the latter is found to be considerably the stronger and more lasting of the two reflexes. In other words, right nystagmus has its dominant cause in the right ear, and left in the left. For convenience of reference, we may say that, when the crista is distorted towards the utricle, it is positively stimulated, and when towards the canal negatively, the positive stimulus being the stronger. Thus the rotatory chair may be used as a means of testing the relative health of the two labyrinths. Deaf mutes and others in whom both labyrinths are destroyed do not react to rotatory or other stimulation.

There are, of course, but three dimensions, and

therefore but three pairs of dimensions or planes in which rotation can take place, but in each plane rotation can take place in two directions-viz., with and against the hands of a clock. There are therefore six ways in which rotation can happen, and in each plane the corresponding canal is stimulated more actively on one side by rotation in one direction, and on the other side by rotation in the other direction. In all cases it is found that the stimulation is greater when the crista is distorted towards the utricle than towards the canal. Hence it is of importance that when a canal is stimulated positively on one side, the functionally corresponding one on the other side should be negatively stimulated. In this way the two horizontal canals are functionally paired, and the anterior canal of one side is paired with the posterior canal of the opposite side. Professor Crum Brown has drawn attention to the very elegant point that the existing arrangement of the canals on both sides of the body is the only possible one whereby this condition can be satisfied while preserving bilateral symmetry.

From what has been said it will be seen that by the rotating chair we can test the relative health of the two labyrinths, for when brought to rest after left turning, the right labyrinth is chiefly in function, and after

right turning the left.

Rotatory nystagmus can hardly, if at all, be controlled by the will, while horizontal nystagmus is greatly shortened if the patient looks at or "fixes" an object.

If horizontal nystagmus is to be observed, it must be done by putting a pair of opaque spectacles on the patient; the reaction is then unhindered, as there is nothing for the eyes to fix.

It has long been known that syringing the ear with too cold or too hot water was liable to cause giddiness, and even vomiting. The explanation is still new, and offers a striking confirmation of the theory of the function of the semi-circular canals.

If, while the head is erect, a stream of cold water be run into the right ear, it is found that rotatory nystagmus to the left, the opposite side, takes place after a minute or so. The cold water causes cooling of the vestibule at its outer side—i.e., in the neighbourhood of the ampulæ of the anterior and horizontal semi-circular canals. This causes the endolymph to condense, and therefore to fall; the horizontal canal lying at right angles to the movement will be unaffected, but in the anterior semi-circular canal there will be established a convection current moving as if the head were rotating in the direction of the hands of a clock—i.e., to the left, and therefore we get a rotatory nystagmus to the left, the opposite side. In the same way syringing with water above the temperature of the body causes nystagmus to the same side.

Since, in obedience to gravitation, movement of the endolymph under influences of heat or cold must always be in a plane vertical with regard to the earth, the nystagmus evoked will always be in the same plane. The name by which it is described will, of course,

vary with the position of the head with regard to the earth. Thus, if the patient lies flat on his back, and the right ear be syringed with cold water, he will get a nystagmus still vertical as regards the earth, but it will be caused by the horizontal canal, and will be a left horizontal nystagmus, since the endolymph moves and the ampulla is distorted as if the patient were being rotated to the left, round an axis run through the centre of the body. A moment's consideration will show that if the nystagmus is evoked by caloric means, the external auditory meatus must always lie in the plane of the nystagmus; hence caloric nystagmus can never be evoked in the sagittal plane.

For this test cold water is better than hot, for two reasons. In the first place, people tolerate temperatures many degrees below the normal, while the upper limit is very soon reached, and, of course, the greater the difference of temperature between the water and the body the greater the effect. Secondly, when used in the upright position the cupula is positively stimulated.

As before mentioned, if the eyes are made to look in the direction of the quick movement, the nystagmus is increased, while if they are made to look in the opposite direction, it is diminished or suppressed. Now it will be found that with the increase of nystagmus the sensation of giddiness is increased, and conversely. This points to the nystagmus as the cause of the giddiness, and here we have a simple remedy for that distressing symptom. When we find out the direction of the nystagmus—i.e., of the quick movement—the patient should be directed to look to the opposite side. years ago, at one of the bazaars in Dublin, there was an ingenious—some said a diabolical—contrivance, called a "Topsey-Turvey House." This was a canvas room, with pictures, fireplace, and windows painted on the walls. A steel bar passed through the middle of the room, on which were fixed a table and chairs, where the people who had paid for admission were seated at a convenient distance above the mock floor. When the seats were occupied, the room was revolved round the steel bar as an axis, with the result that the most dis-tressing giddiness was produced in return for the money paid. Here nystagmus of vestibular character—viz., rhythmic, was caused by ocular means, without any disturbance of the vestibulary apparatus. This furnishes us with a proof that the giddiness may entirely depend on the nystagmus. Needless to say, sitting on a fixed chair with closed eyes would not have evoked it. I knew of a lady who could not take a walk near the sea without suffering from sea giddiness, and the story goes that she was once actually seasick on an openwork iron pier. This must have been the result, in a neurasthenic, of giddiness, the result of ocular nystagmus from looking at the motion of the waves. I have found it a valuable plan when at sea to stay on deck somewhere amidships, and, keeping as vertical as possible, fix my eyes on the horizon. Nystagmus is thus avoided, and no contradiction between the observations of the eye and labyrinth takes place. The only influence uncontrolled is that of the maculæ, but it is probable that this is not so important.

The vestibulary apparatus is susceptible to toxic

influences.

In my own case, long before I knew the reason why, I noticed that, when feverish, I always evoked a feeling of giddiness by looking sideways, and I can now give a fair guess as to my temperature by the discomfort occasioned by such a look. The explanation presumably is that the toxines cause both the fever and the labyrinthine irritation, and that the nystagmus, and therefore giddiness, is evoked by putting the eye muscles in tension. There can be little doubt that the disturbance of equilibrium under alcohol is due to its toxic effect on the labyrinth. I have observed spontaneous nystagmus to both sides, i.e., to the right on looking to the right, and to the left on looking to the left, under what was described by the patient as quite a moderate dose.

If, therefore, poisonous matter circulates in the blood, and by affecting the labyrinth gives rise to giddiness, giddiness is a possible result of toxæmia. And since the stomach is the natural portal through which poison gets into the body, it is no wonder that one of the most prominent effects of giddiness is vomiting, for by this mechanism the presumed source of

disturbance is eliminated. We thus see that the brain in sea-sickness is really hoaxed by the vestibule, through being incapable of distinguishing between a mechanical and a chemical cause of giddiness, the result being that the last meal, however innocent, is foolishly heaved overboard for a Jonah.

The chief accompanying phenomena of nystagmus

are the following:-

It appears to the patient as if external objects were moving in the direction of his nystagmus. Thus with right rotatory nystagmus external objects appear to him to fall to the right. The reason for this is that the quick movement is too rapid for any ocular impression to be made, while during the slow one, with the eye, as we say, rotating towards the left, a procession of images is formed on the retina, such as would happen if the objects were actually falling to the right.

He feels as if he were moving in the same direction, that of the quick movement. For though, in the example taken, the objects appear to be falling to the right, they do not change their relationship to him; his natural impression, therefore, is that he is falling with them. To this it must be added that the conditions in the labyrinth are the same as if he was actually falling, and in so far as the impression of this reaches the cortex, it must contribute to that sensation. Feeling himself to be falling to the right, his natural impulse is to correct this, and so his actual movement is in the direction opposite to the quick movement.

If severe in degree it occasions vomiting. This is less true of horizontal than of vertical or rotatory

nystagmus.

The vestibulary apparatus may be stimulated electrically by a continuous current of about 5 or 6 m.a. through the temporal region. If the cathode is placed in front of the tragus, nystagmus toward the same side is evoked. This method is not of much utility.

Mere air pressure transmitted through the external auditory meatus will also act as a stimulant, but in order that this pressure should be sufficient, some pathological change in the bony capsule of the internal ear must have taken place, such as abnormal mobility, or defect of the foot of the stapes, or an erosion by chronic middle ear disease into some part of the labyrinth.

Owing to our better understanding the physiology of the labyrinth, it is now possible to effect some classification of its diseases, though it must be admitted that our knowledge of the subject is still in its infancy. Complete destruction of the labyrinth apparatus may result from trauma, such as fracture of the base of the skull, purulent infection from middle ear disease, labyrinthine hæmorrhage, syphilis, or acute diseases such as whooping-cough, or without discoverable cause.

When such a lesion occurs in a young child, the prostration and vomiting resulting from the giddiness frequently mislead to a diagnosis of a "gastric attack."

From whatever cause arising, acute destruction of the labyrinth is characterised by complete loss of hearing, severe nystagmus to the sound side, and consequent disturbance of equilibrium, giddiness, and vomiting. The irritability, if tested, will be found to be diminished or abolished. The patient lies on the sound side, thus avoiding the necessity of looking towards that side, and thus increasing the giddiness. In two or three days the giddiness, nystagmus, and vomiting subside, but neither the irritability nor the hearing power ever come back.

Inflammation of the labyrinth may take place without destruction. Serous labyrinthitis, as it may be termed, runs a slower course. At first it has for itsonly symptom spontaneous nystagmus to both sides. Then systagmus to the diseased side, with giddiness and increased irritability, supervenes. In the third stage the nystagmus is toward the sound side with diminished irritability, the hearing remaining positive all through. The disease then usually retrogresses through the same stages until normality is reached at a time varying from a week to a month, but in one case under my cate the affection progressed until after a year the hearing power became entirely lost on that side, and the irritability also lost, the giddiness and spontaneous nystagmus disappearing gradually. This patient came under my observation late in the course of her case, and treatment had no effect. In

another case the patient, otherwise healthy except that she had atropine rhinitis without fœtor, became absolutely deaf on both sides after three months. During this time she suffered from the most distressing giddithis time she suffered from the most distance. After ness and vomiting accompanied by nystagmus. After two months' daily treatment with pilocarpin hypothesis have been became almost normal. The question as to how destruction of one vestibule can cause nystagmus is not easily answered, but we may regard both labyrinths as sending some stimuli towards the centre, which neutralise one another. In this way, with increased irritability, we get nystagmus to the diseased side, while when the irritability is lowered the opposite stimulus being uncompensated, the nystagmus is to the sound side.

Nystagmus from intracranial causes has long been known, and it is important to be able to differentiate

between the two classes.

If there are other intracranial symptoms present, such as palatal and facial palsy, as happened in one of my cases, the diagnosis is easy.

If, with an unirritable labyrinth, we have spontaneous nystagmus to the diseased side, it may be assumed that the labyrinth is healthy, and the lesion is inside the cranial cavity, for a destroyed labyrinth cannot cause nystagmus to its own side.

If with an unirritable labyrinth we have marked spontaneous nystagmus to the opposite side, it may, of course, have its origin in the labyrinth of the affected side, but, if so, it must be the first effect of destruction of that labyrinth, and must cease in a day or two, while if the origin is intracranial it will persist with the

# THE NATURE OF SICKNESS AFTER ANÆSTHESIA, WITH SUGGESTIONS FOR ITS TREATMENT, (a)

BY J. BLUMFELD, M.D.CANTAB., Senior Anæsthetist to St. George's Hospital; Hon. Anæsthetist to St. Mary's Hospital, London.

THE subject of sickness after anæsthesia has a practical interest for all those who, like members of this Society, are responsible for the condition of patients after operation, whether they have themselves either given the anæsthetic, performed the operation, or done neither the one nor the other. I make no apology for bringing this subject before you, although it might be thought that an anæsthetist has little opportunity of seeing the after-results of his handiwork, and that, though he is the main instrument in causing sickness when it occurs, yet he has little opportunity of seeing in what cases it does occur or of treating it when this is the case. To me, however, the after-results of anæsthetics have a particular interest, and I have long been in the habit of finding out what has happened to a patient afterwards or of seeing for myself. In hospital, of course, it is perfectly easy to observe for oneself, and in private cases when this is not convenient one can generally be furnished with a reliable account from the practitioner or surgeon in charge, or else from the nurse. The private cases are in this matter perhaps more important than hospital cases, first because the subjects in whom after sickness is a real obstacle to a favourable result are more common in private practice than in hospital; and secondly, because the hospital patient is less upset by sickness afterwards, and is more apt to take it as a matter of course. This brings me to the question of the prevalence of sickness, and here I would say that writers on the subject appear to me to over-estimate the proportion of cases in which sickness follows an anæsthetic. The various statistics that have been compiled are not of much value, for this reason, that just what is meant by sickness is not always clearly stated.

Here are some figures collected in the Report of the Anæsthetic Committee, British Medical Association, IQOI:-

2r,585 cases ... 3,406 vomiting in various degrees. ČHCl₃ ... 11.6 per cent. vomited \*\*\* ... 24.7 22 Gas and ether ... 15.01 A.C.E. ... 18.4

(a) Paper read before the Chelsea Clinical Society, April 20th, 1909.

Marcus Gunn, in 4,056 ophthalmic cases, found that 1,902 vomited. Summing up available figures, T. D. Luke finds

CHCl<sub>3</sub> gives 15 per cent. A.C.E. ,, 25 ,, E ,, 40 ,,

In this paper, when I speak of sickness after anæsthesia, I mean any vomiting or retching which occurs after the patient has become conscious. Before consciousness has returned any such act is, of course, a source of no discomfort to the patient, and is, moreover, being never of a prolonged or very violent character, often an advantage rather than the oppo-site: after the use of ether, for instance, it is a common occurrence and one not to be prevented or regretted for the patient to vomit, just after the anæsthetic is withdrawn, the mucus and saliva that has been swallowed. This is so little to be deprecated that some administrators, indeed, urge that the process should be imitated in all cases where ether has been used, by washing out the stomach with water directly after the administration has stopped. Indeed, one authority recommends prolonged lavage of the stomach for about half an hour, for example, three to six gallons of water being used, a pint at a time. This is poured into the stomach and syphoned out. He believes that in this manner all the ether can be washed out of the patient's blood. I have never tried that method, nor do I think it is rational. If ether were excreted only by the stomach there would no doubt be much to be said in favour of this stomach washing. The fact is, however, that ether and other anæsthetics are excreted not largely, if at all, by the stomach, and our efforts at freeing the body of them as soon as their work is done should not be primarily directed to the stomach at all. In alluding to treatment, however, I am putting the cart before the horse, and must first discuss the causation of sickness and see to what extent we know the nature of that which we shall endeavour to treat. Firstly, then, with re-gard to the stomach we have to remember that the mucous membrane does not secrete unless stimulated. The condition is different from that which holds, for instance, in the case of the kidneys, from which urine escapes in a regular, though intermittent, manner along the ureters and into the bladder. In the stomach such secretion takes place only on stimulation, and the best stimulus is the natural one, i.e., food. The nerves of the stomach come from the vagi and splanchnic plexuses, and end beneath the cells of the mucous membrane; they have not been traced into the epi-thelial surface. It is conceivable that anæsthetics which are being carried by the blood might, when they reach the stomach circulation, stimulate the nerve endings and cause secretion, just as happens in the case of the salivary and buccal glands. We should then have the unusual fact of the stomach secreting, although there was nothing in it. Physiology teaches us that this is not, however, a very unusual occurrence, and that the nervous mechanism of the stomach may be excited and secretion aroused by impressions upon the central nervous system, as, for instance, the sight or smell of food to a fasting man. The stomach, sight or smell of food to a fasting man. The stomach, in fact, can be excited to secrete either locally by the presence of food or through the central nervous system, as in the case referred to. Anæsthetics might cause secretion in either of these ways, but, on the other hand, they might inhibit the process, as we know they do in the case of secretion of urine and, indeed, in the case of metabolism generally. Similarly with the act of vomiting we have to recognise both a local and a remote causation. Vomiting may we know be a remote causation. Vomiting may we know be caused by direct action upon the mucous membrane of the stomach or by impulses emanating from the vomiting centre in the medulla oblongata. This centre is closely related with the respiratory centre, and like this centre it may be excited in a reflex manner by stimuli applied to peripheral nerves as, e.g., when vomiting is induced by tickling the fauces. The vomiting of intestinal obstruction is also of this reflex nervous nature, and not a regurgitation, for it may be prevented by division of the mesenteric nerves, and it occurs even when the bowel is empty. In these cases

of reflex vomiting, another familiar example of which is the vomiting associated with the passage of calculi, the afferent impulses reach the centre by vagi and splanchnic branches. Now, the centre may be excited, not only reflexly, as in the foregoing instances, but just as may the wall of the stomach, it may be excited directly by the action upon it of certain drugs. over, it is excited in some cases of disease within the cranium; and, lastly, it may be excited by impulses reaching it from higher parts of the brain, as in cases of vomiting from smell, taste, or violent emotion. Emetics like tartar emetic appear to act directly on the centre, for they produce vomiting when a bladder has been substituted for the whole stomach. Others, such as mustard and water, act by irritating the gastric membrane. There is another way in which vomiting may arise that I have not yet mentioned, this is in connection with circulatory depression, as in the vomiting that so often terminates a fainting attack. Taking into consideration these various ways in which vomiting may be caused, and bearing in mind the action of anæsthetics as we know it to have effect upon the nervous system we are brought to this conclusion: Vomiting due to an anæsthetic drug which is in circulation throughout the body must arise either (1) by the direct stimulant action of this drug upon the nerve endings of the stomach, or (2) by its direct action upon the vomiting centre, or (3) by causing circulatory depression to such an extent as to bring about cerebral anæmia. Now, with regard to the stomach, we have a certain amount of evidence, both clinical and experimental, that though the condition of this organ plays a part in the causation of vomiting from anæsthetics, yet it is not the chief organ concerned. We know from experimental observation that during anæsthesia the mucous membrane of the stomach is saturated with the anæsthetic, brought to it, of course, in the circulating blood. Thus both the mucous membrane and the glandular and muscular tissues of the organ are subjected to the action of the drug. The nerves also are under its influence. We know from clinical evidence that the condition of the stomach as regards fulness or emptiness plays a part in the occurrence or not of after sickness. At the same time it must be stated that one authority at least disputes this and maintains that vomiting is no more likely to occur if a patient is fed shortly before operation than if he is not. The experiment is one that is made for us occasionally in the case of emergency operations, and my own experience is that when the stomach is full at the time of administration vomiting invariably occurs either during or just after the administration of the anæsthetic. Indeed, one of our chief reasons for anæsthetic. Indeed, one of our chief reasons for believing that post-anæsthetic vomiting depends mainly upon a central effect and not upon the stomach itself is our incapacity to control it even by the most thorough care of the stomach. Thus we may ensure by careful dieting, regulation of the bowels, and a proper interval after the last food and before the anæsthetic that the stomach is really empty at the time of operation. We may then by washing out the stomach with water before return of consciousness remove any secretion that has taken place in the stomach during anæsthesia by reason of the stimulating effect of the anæsthetic upon the mucous membrane. We should now, if the stomach alone were responsible, get no further vomiting, provided that nothing were put into the stomach to excite secretion. Unfortunately, the facts do not bear out our hypothesis, and such treatment as this, although it diminishes the number of cases in which vomiting occurs does certainly not abolish its occurrence.

Allied to this treatment by washing out the stomach is a measure based on the same idea that, viz., of removing the anæsthetic which is presumed to be excreted into the stomach. This measure consists in the systematic administration of large quantities of water before operation. Four ounces of cold water are given every four hours until two hours before operation, then 10 oz. are given and, again, 10 oz. half an hour before operation. In two series of cases treated in this way there were, in the first series of 35, four cases of vomiting. S. E. Gunn in the second series of 40 cases found that twelve vomited in the ordinary way; nine did not vomit at all, and twelve vomited

slightly, or only once. He states that those who had had anæsthetics previously pronounced themselves much more comfortable when this treatment was adopted. Such figures as these are obviously of little value without further details. One wishes to know what operation is performed in each case and what anæsthetic is employed. Both these factors have an influence on the occurrence or not of vomiting. tain operations, particularly in my experience those upon the kidney, and upon the pelvic organs in women, are more likely to be followed by sickness than others. I may mention here that years ago Lord Lister stated his belief that operations dealing with Lister stated his belief that operations dealing with the ovary were especially liable to be followed by vomiting. The different behaviour of different anæsthetics in this respect is familiar to you all. It is the common opinion nowadays that CHCl<sub>3</sub> causes less sickness than E, and it is interesting in this regard to notice that when the latter drug was first introduced, one of the chief advantages claimed for it was the diminished frequency with which it inhelation the diminished frequency with which its inhalation was followed by sickness as compared with the commonness of the latter after chloroform. The explanation of this discrepancy lies in the method of administration. Ether by an open method, which was the original old way, now once again extolled, is certainly followed less by sickness than are the newer closed methods, whatever may be the other disadvantages belonging to the original method of administering the drug.

administering the drug.

The true facts as regards CHCl<sub>3</sub> and E in this connection are, I think, these: vomiting is more often absent altogether after the use of CHCl<sub>3</sub> than it is after the use of E; but, on the other hand, really serious vomiting, going on, for instance, for days, is almost always the sequel to chloroform anæsthesia, and scarcely ever to that from ether. I cannot enter here upon the vexed question of the so-called delayed CHCl<sub>3</sub> poisoning, which would require a long paper by itself, but it is, I think, quite rational to regard all cases of vomiting after chloroform as being of the same nature as these pronounced cases, the effect in one case being slight and transitory, in the other more pronounced and long-lasting. With ether the typical vomiting occurs early and is soon over. This corresponds with the volatility of the drug and with the much less extent to which we know it to act upon the tissues than is the case with chloroform. There are some persons who are made sick by chloroform although they are not by ether, although in accordance with what I have said before the opposite is more

Occasionally it may not really be the difference in the drugs that is responsible, but the necessary difference in the way they can be administered. I mean that in the case of CHCl<sub>3</sub>, anæsthesia cannot be induced without the patient being conscious of the anæsthetic. Whereas in the case of ether by preliminary use of nitrous oxide this can, of course, be accomplished.

often the case.

An interesting example of this occurred to me not long ago. The patient, a lady, æt. 44, had undergone an iridectomy, for which she took chloroform given by an expert anæsthetist. The vomiting that followed was so violent and prolonged that to it was attributed a cataract of the lens which followed on the operation. It became necessary to operate for removal of this cataract, and the surgeon anticipated so much difficulty from adhesion that he did not think it wise to attempt the removal under a local anæsthetic. The patient assured me that if she smelt chloroform it would make her sick, and I have no doubt it would have done, for she was not at all a fanciful or neurotic person. I promised her she should smell nothing whatever except a little pleasant scent. This was accordingly sprinkled into the facepiece of a Clover, and she was fully anæsthetised by nitrous oxide, followed by just enough ether to tide over the transition to chloroform. The operation, which was a difficult one, was done under chloroform, and lasted 17 minutes. The natient did not vomit at and lasted 17 minutes. all, and was, except for a few minutes after the return of consciousness, when she thought she was going to be sick, quite comfortable throughout conJUNE 16, 1909.

valescence, and highly pleased with herself. This was a case, if one may judge by the bare facts, in which the method of administration, and particularly quick-ness and pleasantness of the induction of anæsthesia were essential factors in avoiding after-effects.

I have mentioned as a third possible cause of post-anæsthetic vomiting, circulatory depression. Depres-sion of the circulation, accompanied by a certain amount of diminished blood supply to the brain, occurs in the course of most kinds of anæsthesia; moreover, the act of vomiting is, as we all know, generally directly preceded by a pallor which indicates the low ebb at which the force of the circulation has arrived. Yet it would, I think, be difficult to maintain that this condition is the primary state which causes postanæsthetic vomiting. In the first place patients under ether may vomit, as we must all have seen at times, whilst their circulation is actually in-so to speakfirst-rate going order; a full pulse, a deep red face, and a vigorous respiration up to the very point of vomiting; showing that a depressed circulation is not immediately to blame in the matter. Moreover, patients who have been ill long, and are anæmic, weak, and with very poor circulatory power often go through even long of erations without any subsequent vomiting. We may put this cause aside then also, and regard post-anæsthetic vomiting as a central effect produced mainly by the direct action of the anæsthetic drug upon the vomiting centre. Another argument in favour of this view is the consideration that, broadly speaking, patients vomit only when they are lightly under an anæsthetic. They may vomit in the process of induction if this takes place toe slowly; they may vomit during anæsthesia if this is of too light a degree, and thirdly they may vomit when, no more being administered, they are beginning to recover from the effects of the drug. Now this course of events corresponds with what we know of the action of anæsthetics upon other parts of the central nervous system. Their general action in this respect is at first to stimulate, and then with increased anæsthetic effect to deaden nervous action. So too with the vomiting centre; at first a stimulation, resulting in vomiting if the increased action is not rapidly proceeded with, which results in paralysis of the centre. During recovery we reach again the stage of stimulation with consequent vomiting. If we agree then that post-anæsthetic vomiting is a central effect, unfortunately we are no nearer the pertinent question "why do some patients vomit after are the pertinent." "why do some patients vomit after anæsthetics, and ethers not?" Putting aside the various considerations which I have alluded to, such as the nature of the operation, of the anæsthetic, the duration of the anæsthesia, the previous preparation of the patient, there are still one or two points to be mentioned before we confess that we cannot further answer this question. A practical point is the extent to which the patient is moved when operation is over. It is astonishing how constantly the moving of a patient from operating table to bed, if cerelessly performed, and particularly if the head is allowed to flop about, will be immediately followed by vomiting. Moreover, I have been told by a well-known surgeon who had himself to undergo several operations that in the semiconscious stage of early recovery he felt quite comfortable, unless an attempt was made to alter his position in bed—then he was invariably sick. This is a point in which, I think, nurses are not sufficiently schooled. They should be told most emphatically that when the patient is back in bed he should not be shifted an inch unless for some important reason until consciousness has completely returned.

The position in which he is placed when put back to bed is thought by some to be of great importance. Some surgeons attribute a great deal to the sitting position. The patient after an abdominal operation is put back to bed sitting almost bolt upright, a special arrangement of support beneath the thighs being employed to keep him there in addition to pillows behind the back and shoulders and head. It is held, I believe, that in this position anything inside the stomach is more likely to pass on through the pylorus than when the patient lies down. Certainly if sickness actually occurs it is far less strain on the sitting than on the lying person. Supposing now that all the

points referred to, preparation, proper choice of anæsthetic, minimum quantity of the anæsthetic, careful movement of patient, proper position and quiet careful movement of patient, proper position and quiet in bed after operation, have all been attended to in two different persons, it may yet happen that one of them will be entirely free from sickness and the other vomit abominably. How can we explain this? At cresent, gentlemen, I believe we cannot, and we talk of different idiosyncrasies. No doubt we shall discovere come day what the manning of such idiosyncrasis. cover some day what the meaning of such idiosyncrasy is, and it may be that a tangible chemical difference will be elucidated along the lines of work which various investigators are pursuing in connection with delayed chloroform poisoning. At present clinically we have a few empirical facts that guide us in practice, but the scientific bearing of which we cannot yet discern. For instance we know that those who have been accustomed to considerable amounts of alcoholic drink over a considerable period of time are our best patients from the point of view of aftersickness. They seem to have a real immunity against this effect of anæsthetic drugs. They are intmical to their action in every way as we all know from the difficulty that may be experienced in anæsthetising such individuals, and the extreme liveliness of their reflex excitability throughout anasthesia. But what is the secret of this immunity we do not know. If we but did we might be able to confer it temporarily upon our abstemious, but after anæsthetics, unhappy patients.

Again we know that vomiting is quite unusual with very old patients, and also with very young ones. Generally speaking young adults are bad subjects from the point of view of vomiting afterwards-often with these subjects, such as boys about 15 years old, for example, there is much mucous secretion; when that is the case, to wash out the stomach once before recovery lessens the tendency to vemit.

To speak for a moment of exceptional instances of vomiting. In my own experience they have occurred only in one class of subject. This is the neurotic emotional unstable woman of about thirty who has led a fast life. In this class of subject I have twice seen vomiting after operation so severe and so long lasting that the chances of its leading to death from exhaustion seemed very grave indeed. In one case exhaustion seemed very grave indeed. In one case there had been a laparotomy with removal of double pyosalpinx-that is to say an operation after which vomiting might be expected. The operation had not taken very long, however, and was well borne. Vomiting started almost as soon as consciousness returned, and there was not that delay which is usual in the delayed CHCl<sub>3</sub> cases; water by the mouth was allowed, and a rectal injection was given containing 10 grains of aspirin. I had asked that this might be given early after operation because the patient was obviously, before taking the anæsthetic, of a very highly strung, nervous kind, and I think aspirin by the bowel after anasthesia often ensures a long space of time for quict recovery in these people. However, in this case it apparently did no good, for the vomitin this case it apparently did no good, for the vomiting continued so frequently and so violently that on the fourth day the gentleman in charge of the case asked me if I would go and see the patient with him. I found her not so exhausted as I expected, but in a very restless talkative condition, and with a pulse over 100. There was nothing to incriminate the abdomen, as a cause of the vomiting. We treated her with injections of 1/6 gr. of morphia every two hours, and after three injections there was no further vomiting, whether in spite of, or because of the injections, it does not seem possible to say.

Now in the other case to which I referred, which was throughout very similar, there was this interesting

addition, viz., that the patient had several anæsthetics from all of which she recovered only after appearing to be in extremis from vomiting, and one of these anæsthetics was a short administration of nitrous oxide and oxygen—this, I think, points very strongly to the nervous nature of such cases as these. In many cases I believe it is good practice to give an enema containing a large dose of bromide before consciousness has fully returned. The practice of giving morphia beforehand in order to reduce after sickness I have not found successful. The most rational way

to treat and prevent after-sickness, according to present knowledge, appears to be to promote in way the elimination of the circulating anæsthetic. That is to say the patient should be kept warm that the skin may act freely, and renal secretion should be helped. For this purpose saline enemata are, I believe, of great value, and one should be slowly introduced as soon as the patient is back in bed. In some hands large quantities of saline are introduced slowly under the skin for long periods of time after severe operations, and it is claimed that not only is shock diminished in this way, but after sickness immensely less frequent. Whilst elimination is thus going on the less put into the stomach the better. There is no call for anything at all except through thirst, and this is little trouble if enemata or subcutaneous injections are used. Washing out the mouth with glyco-thymolin or lemon juice and water is pleasant for the patient, and helps to allay feelings of thirst. On the theory that post-anesthetic vomiting arises through cerebral ædema calcium lactate to lessen transudation of the blood serum has been recommended. I have had no opportunity of testing this. Preventive treatment with glucose, based on chemical theories explaining delayed chloroform poisoning has been given a trial at St. George's Hospital; the results do not show any marked alteration of the ordinary percentage of cases of after-sickness. in estimating the value of any method a very long trial is necessary, for the number must embrace many examples of all kinds of subjects. At present there is no doubt that the patient's personal peculiarity, on whatever it depends, is a very determinant factor in the question of after sickness. Nevertheless, gentlemen, I hope I have indicated that much may be done by proper selection and administration of anasthetics, and by proper treatment before and after, to alleviate what is often an extremely distressing, and what will in the future, I hope, be a far less common complication during recovery from anæsthesia.

### THE STATE AND OTHER RELATION-SHIPS OF MODERN DENTAL SURGERY. (a)

By H. R. F. BROOKS, L.D.S.EDIN., GLAS., AND I., Hon. Dental Surgeon to the Horton Infirmary.

THE deplorable state of the teeth of civilised races has long been recognised; the evil is an increasing one and at the present time is so general that there are few who escape its ravages. A variation from the economy of Nature at once so important and so well-nigh universal, could not fail to have significant results beyond any temporary or individual inconvenience. I do not propose to discuss the influence of deterioration of the teeth upon the evolution of the race, or to do more than suggest the converse hypothesis, but without entering the realms of speculative theory at all, it may be asserted that there are few diseases of which an unhealthy mouth may not be a direct or contributory cause. Dyspepsia, with the many ills that follow in its train, at once suggests itself as a well-known example, but there are other of the more common and serious diseases whose dependence upon a faulty condition of the organs of mastication is not so generally recognised. The mouth, even in a normally healthy state, offers a favourable medium for the conveyance of pathogenic organisms, but the chances of their development and infection of susceptible tissues are infinitely increased by any departure from this condition. The possible agency of dental caries in the production of tuberculosis, for instance, cannot be disregarded, and care of the teeth is one of the necessary preventive measures to which the Local Government Board (or the suggested Minister of Hygiene) should direct attention in any future official circular on the subject. In this country it is largely owing to the persistent efforts of the British Dental Association that notice is being attracted to the grave

effects of dental caries upon the health and physique of the nation.

The examination of large numbers of school children (and in this connection the excellent work of the School Dentists' Society should be mentioned) has conclusively shown that those with decidedly defective teeth are almost invariably amongst the most unhealthy. On the other hand, and to prevent any confusion of cause and effect, experimental denta-treatment has been followed by a marked improvement in the general condition—individually of the children. and collectively of the particular school. portant data are afforded by the wholesale rejection of army recruits because of defective teeth, and the acknowledged gain to the State resulting from the tentative arrangements for dealing with some of these cases; by the report of the Inter-Departmental Committee on Physical Deterioration; and by the action of the Board of Education leading up to, and following the medical inspection of school children. When to these are added the conclusions of the Sub-Committee of the Education Committee of the London County Council on Medical and Surgical Treatment (of which the Hon. Secretary of this Association was so useful a member) it is manifest that attention is being irresistibly drawn to this difficult problem, although its

full significance is by no means realised even yet.

"Knowledge comes but wisdom lingers." Still, the recognition of an evil is the first step towards its remedy. Speaking here this morning to an audience of experts, I need not say that there is a remedalthough it must be confessed that there are difficulties in the way of its application. The individual who is able to pay the fees can be treated—very successfully treated—by the trained and skilled dentist; a few—unfortunately a very few—of the poorer members of the community may be assisted by generously reduced charges, or by Dental Aid Organisations (of which we are to hear something during these meetings), of by hospitals and dispensaries. There remains a still greater proportion of the comparatively or the very poor, for whom there is no provision by the charity of either profession or public. Amongst them are a relatively large number of those to whom, more than any, sound teeth and healthy mouths are essential the physically unfit, the ill-fed, the badly housed and clothed—those who fall an easy prey to the disease associated with poverty and dirt—those whose impoverished and hereditary taint will be transmitted with the most reckless prodigality and improvidence. to succeeding generations. If, as in the history of pasticivilisations, not only the happiness, but the veriexistence of a nation, may be threatened by the deterioration of the units composing it, there is cause-nay more, there is urgent need—for intervention the State, even although the possible issue be State Dentistry in some shape or form.

The systematic inculcation and practice of simp. methods of hygiene would do much to limit the evi and such instruction must always form part of an suggestions for its cure, but, apart from this, there and there can be, no alternative to the adoption measures for treatment by properly qualified dentists It is frequently stated, and stated with some appear ance of reasonableness, that our numbers are hopeless. insufficient for the purpose, and that the entries a the dental schools offer no immediate prospect of an satisfactory adjustment, but it is probable that, : both respects, the resources of the profession a greater, and might be more extensively utilised the seems to be generally supposed. There is one dire tion, at any rate, and that along the line of least : sistance, in which they should be adequate to desuccessfully with a large amount of incipient diseaand very greatly to restrict many of its cumulative effects. The children, of course, offer this most remising field for organised dental service.

For the operation of any definite scheme, whether it take the form of school clinics, or recognised denisurgeries, or one method, State or rate aid, or possibly appropriate the composition of the composi

support, seems inevitable.

If I have emphasised the necessity for some national

<sup>(</sup>a) Abstract of Inaugural Address delivered before the Annual General Meeting of the British Deutal Association, Birmingham, May 29th, 1909.

provision for the care of children's teeth, it is because, whilst there is no physical evil so prevalent as dental caries, or possibly so diverse in its consequences, there is probably none the treatment of which, if undertaken in its early stages, would secure results so important and comprehensive, at a cost so comparatively small.

Amongst those prospective results may be included not only a decisive check to the forces of deterioration, but a sure, if gradual, racial improvement. It is true that degeneration is ever a more easy and rapid process than regeneration, that facilis descensus averni, but it is quite possible that in the course of long periods of time a return to type might be secured, and that the dental tissues, which in man's earlier history were the most enduring of the human organism, might again outlast the individual. Need I say that this ideal future, in which the dentist will be only a memory of a troubled past, is yet far distant.

There is another direction in which the interests of the public and the dentist alike call for the intervention of the State. Those important issues which depend upon the treatment or neglect of dental disease make it absolutely essential that, so far as the State can determine, the treatment shall be the best that modern science can provide—that it shall be given by those, and by those only-whose qualifications have satisfied the standard recognised by law, as well as by common sense, as needful for registration.

Unfortunately it is notorious that dentistry has always offered a lucrative field for the enterprise of the ubiquitous charlatan, ever alert to take advantage of the proverbial ignorance and credulity of the public in all matters affecting its own health, and prepared with every variety of subterfuge to imply that he is what he is not, and what he may not call himselfa person specially qualified to practice dentistry. Recognising this evil of whose extent and consequences it has unequalled opportunities to judge, this Association urges the necessity for appropriate means to deal with it.

In proportion to the greatness of the legacy of science and opportunity which we in these early days of the twentieth century enjoy, are our present responsibilities, and our obligations to those who come after. It may be there are few of us who can hope to make any notable contribution to the wealth of this inheritance; the share of most of us may be no more—it certainly should be no less—than the honest attempt to discharge the duties of our ordinary everyday work. But, if this be all, the part is surely no ignoble one; to serve mankind, to relieve its sufferings, to lessen its ills, to help it forward to the ideal existence, these are privileges of the calling we have chosen. And it is as we most untiringly pursue those objects, as we most faithfully discharge our duties to those who entrust themselves to our care, that we shall most nearly approach the goal of our professional life, that we shall most closely realise the aspirations of our Association, both of them so well expressed in the watchword of this city and in the motto of this University: "Forward"—Per ardua ad alta.

### OPERATING THEATRES.

ROYAL FREE HOSPITAL.
CASE OF COLOSTOMY. — MR. WILLMOTT EVANS operated on a man, æt. 53, who had been admitted suffering from chronic intestinal obstruction due to malignant disease of the rectum. He had been suffering from gradually increasing constipation for more than a year. The motions had become compressed, or pipe-like, and both with and between the motions blood and mucus were passed. He had no definite pain, but he had found it necessary to take an increasing amount of aperient medicine frequently. He had had two or three attacks of almost complete obstruction, but he had been relieved by copious enemas. He had steadily lost flesh, though the total amount of loss appeared not to have been great. On examination per rectum a hard mass was felt some

three inches from the anus; it extended round the whole circumference of the bowel wall, though it was more marked posteriorly. The lumen was much contracted, and only the tip of the finger could be introduced for about a quarter of an inch, but after that the opening became still smaller. In the hollow of the sacrum some ill-defined masses could be felt, which were probably enlarged lymphatic glands. There was no evidence of any secondary growth in the liver or elsewhere. As Mr. Evans did not consider the local growth to be removable, he decided to per-form the operation of colostomy.

The patient having been prepared and anæsthetised, an oblique incision two inches and a-half in length was made on the left side of the abdomen, parallel to Poupart's ligament and an inch and a-quarter above it, the upper end of the incision being placed on the line leading from the anterior superior iliac spine to the umbilious. The incision was deepened until peritoneum was reached; this was then opened and seized with forceps. As no bowel presented, the forefinger of the right hand was introduced and swept across the iliac fossa from within outwards. It came in contact with a portion of bowel which was drawn out of the wound. This was recognised to be the sigmoid flexure by the presence of the appendices diploicæ and longitudinal muscular bands. It was somewhat distended, but it was easily drawn out of the wound. As much bowel as possible was drawn down until the upper part of the sigmoid was reached. The remainder of the bowel was returned, leaving a loop of some three or four inches outside the body. An opening was then made in the meso-sigmoid, close to the bowel, the obvious vessels being avoided. A silk stitch was then passed through the skin of one edge of the wound, then through the opening in the meso-sigmoid, then to the skin on the other side of the wound, after which it was passed back through the opening in the meso-sigmoid and tied so as to bring into contact the two edges of the skin underneath the bowel. A few other silk stitches were also inserted so as to attach the bowel to the edges of the wound, the stitches being chiefly passed through the longitudinal muscular bands. A piece of "protective" was then placed over the bowel, and the wound dressed with gauze in the usual way.

Mr. Evans said, as for the diagnosis of this case, there was no room for doubt; the clinical history of a gradually increasing constipation, with a narrowing of the diameter of the motions, pointed conclusively to a constriction of the bowel, and the presence of blood and mucus in the motions made it probable that the stricture was due to a growth. Digital examination confirmed this diagnosis, and gave additional information that the growth was carcinomatous in nature. The question then arose: Would it be possible to remove the portion of affected bowel? He thought this could not be done, because the large size of the growth and the apparent involvement of the lymphatic glands in the hollow of the sacrum rendered it practically certain that the growth was much more widespread than even it appeared, and that any attempt at its removal would fail, for it would not be possible to remove it completely, and early recurrence would only follow. The only alternative was colostomy. Mr. Evans was in favour of performing this operation at a comparatively early date of the disease, for he thought that if it were postponed until complete obstruction occurred, the results were much less satisfactory. Moreover, he thought that by providing a higher outlet for the fæces, the rapidity of the growth of the carcinoma in the rectum was retarded, as it was no longer subjected to the irritating influence of the passage of the fæces. Nowadays the only operation of colostomy performed is the left inguinal. was desirable, he considered, to make the incision fairly high up, as had been done in this case. method he had employed to prevent the bowel slipping back was the most convenient, for, so long as the stitch held, the bowel could not return into the abdomen. It was desirable not to make too large an incision through the abdominal wall, for large incisions favour prolapse. Some years ago Herbert Some years ago Herbert Allingham suggested dividing the bowel, suturing the

upper portion to the abdominal wound, and closing the lower portion and returning it into the abdomen. The objection to this practice was that it was extremely difficult to determine which was the upper and which was the lower end; in fact, the mistake of confusing the two was made in one case in which Allingham's method was employed, so that this form of the opera-tion is no longer performed. It was best to defer the opening of the bowel to the third day after the operation. If the distension is very great it may be opened at once, a Paul's tube with a rubber tubing being em-If the opening be postponed till the third day, good adhesions have formed. No anæsthetic is required, and the redundant portion of bowel easily snipped away with scissors. An efficient colostomy truss must be worn, and it is desirable that charcoal and salol be given by the mouth, so that the fæces are less malodorous than they would otherwise be. The diet also should be so chosen as to give rise to as little decomposition as possible. If these precautions be taken, patients have little discomfort, and do not regret that the operation has been performed.

The bowel was opened on the third day, and the patient was able to leave the hospital about a fortnight after the operation, wearing a truss.

OPERATION FOR STRANGULATED HERNIA. - MR. JOSEPH CUNNING operated on a man, æt. 76, who had been admitted with the following symptoms: A right inguinal hernia, from which he had suffered for many years, had become irreducible fourteen hours before admission. There had been neither pain nor vomit-ing; the bowels had not acted since that period. On examination a swelling the size of a large pear occupied the scrotal and inguinal regions; it was tense, curred yet, there were the most incontrovertible signs of strangulation present—namely, that the hernia was tense, irreducible, and without impulse on coughing. The tensity of a strangulated hernia was due to the effects of gradual compression of intestine, which resulted in ædema of that structure, and later in the presence of free fluid in the hernial sac. the presence of tensity in an irreducible hernia was the most certain sign known of strangulation. In older times it was taught that collapse and fæculent vomiting were the classical symptoms, but it was extremely rare nowadays to see a patient who had been allowed to go unrelieved for a sufficiently long period for these symptoms to arise.

As a prolonged attempt to reduce this rupture had been made before admission, it was not thought advisable to make any attempt at reduction except by operation. Another reason for this decision was, that the hernia had been strangulated three weeks previously, although on that occasion it had been possible to reduce it

An incision was made over the inguinal canal and extending inwards and downwards for about an inch beyond the external ring. The sac was exposed and opened, a quantity of blood-stained fluid being found within it. The situation of the constriction was found to be a thick, indurated external ring. This was divided with a hernia knife after passing a hernia director, the direction of the cut being vertical and The strangulated portion of small intestine could then be pulled down, and a careful examination made of it. With regard to this, Mr. Cunning demonstrated that there was no ulceration at the line of constriction, and that, although the bowel was of a deep purple colour, it retained its polish, and therefore gangrene had not occurred. Under these circumstances it was safe to replace it within the abdomen. This was accordingly done. The sac was next isolated as far as the internal ring, ligatured, and removed. The internal oblique and the conjoined tendon were then sutured to the deep part of Poupart's ligament behind the structures of the cord. The cut margins of the external oblique were then sewn together in front of the cord, the skin around being subsequently brought together by a continuous suture without drainage.

Mr. Cunning remarked that the rules laid down as to the division of the constriction applied more especially to cases in which it had taken place at the internal ring. The direction of the division did not so much matter when the strangulation had occurred at the external ring. At the internal ring the incision should be made directly upwards, so as not to risk wounding the deep epigastric artery. In the present case the site of the strangulation was owing to the external ring having been much inflamed and thickened, the result of the constant wearing of a truss. For this reason, when more bowel was forced down, the hardening of the external ring had produced strangulation.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

MEETING HELD FRIDAY, MAY 7TH, 1909.

The President JOHN LENTAIGNE, in the Chair.

BIER'S METHOD OF TREATMENT BY HYPERÆMIA.

MR. R. ATKINSON STONEY read a paper on the above subject. After mentioning the various forms of hyperæmia, he said he would confine his remarks to passive hyperæmia, produced by means of the elastic bandage and suction glasses, more especially in the treatment of septic inflammation, rather than in tubercular disease, as in the treatment of the latter type of cases his experience had been neither extensive nor promising. He described the method of applying the elastic bandage and the suction glasses, laying special stress on the necessity of not producing too great a degree of hyperæmia, as in that case serious harm might be done. He gave the following rules for the application of the bandage:—(1) Place it on the limb as far from the site of the disease as convenient.
(2) Wind it round a broad surface of the limb, to prevent local pressure and pain. (3) Do not bandage with sufficient force to weaken the pulse distally. (4) No pain should be caused in the diseased part, rather any existing pain should disappear. (5) The distal part should be bright or dark red, not blue, and should be warmer than the corresponding part on the opposite limb, not colder. (6) The bandage, for all opposite limb, not colder. (o) the bandage, for all except tubercular cases, should be left in position for two periods of 8 to 11 hours, or one period of 16 to 22 hours out of the 24. In the case of the suction glasses, ordinary aseptic precautions should be ob-A glass of sufficient size should be chosen to leave a margin of 1 in. or more around the inflamed part or opening, to prevent strangulation or compression of the lips of the opening. Pain should not be produced. And, especially where the cup was placed over a superficial bone or firm membrane, excessive pressure should not be used, for fear of sloughing of the parts. Some cases were briefly described illustrating the use of both these forms of application of passive hyperæmia in various conditions.

The PRESIDENT said he had been deterred from the use of the method by the unsatisfactory results got in the hands of some surgeons, but Mr. Stoney had helped to explain some of those results. He had recently been converted to its use for boils, but he had seen a great number of cases of tubercular disease which had deteriorated by the treatment, and in some cases he could not satisfy himself that the dissemination of the tuberculosis had not been in some way due to it.

Mr. L. G. Gunn said he had tried the treatment in cases of knee and wrist trouble, but found it impossible to produce any degree of congestion without pain. He was therefore not surprised at getting no good results. He thought French and English people, and more particularly Irish people, probably felt pain more acutely than the Germans, which might explain the differences in results.

the differences in results.

Mr. W. I. DE C. WHEBLER confessed the same experience as Mr. Gunn, but in cases such as gonor-

Dr. ELLA WEBB inquired as to the effect of the use of appliances advertised for putting on to the cervix of the uterus.

Mr. PEARSON said that the use of the band would seem to lead naturally to the increase of pain, as it was chiefly a matter of tension, but the suction apparatus, by reducing atmospheric pressure, might produce an initial diminution of pain.

Mr. STONEY, in reply, said the worst results had been got by Bier in the knee-joint, for some reason which he could not explain. He did not suggest the treatment in any case where better results, or quicker equal results, could be obtained by operative means. It was in tubercular cases that the greatest difficulty was found in producing the correct degree of hyperæmia. He had no experience of the instruments mentioned by Dr. Webb. The question of tension was difficult to deal with. It was, however, easy to understand that pain, which might be due to irritation of the nerve terminals by toxines produced by organisms, might be relieved by the congestion causing a flow of blood and lymph, and producing a dilution of the toxins.

#### POST-OPERATIVE TETANUS.

Mr. Gunn read a paper on this subject.

The President said the paper was one of the most valuable which had been read before the Academy. He could imagine no more appalling catastrophe to happen a surgeon than to have a case, or series of cases, of post-operative tetanus. He could not help keeping to the belief that the catgut must have been responsible. It was curious that in every case in which the catastrophe had occurred, catgut had been used. It would be important to know what methods of sterilisation had been employed. He had himself been using the iodine catgut for some time, but if he was threatened by the terrible phantom of possible tetanus he would be inclined to give up catgut altogether

he would be inclined to give up catgut altogether.

Dr. KATHERINE MAGUIRE said she had been in attendance on one of the cases mentioned by Mr. Gunn. It was not a case of hysterectomy alone, but was combined with ovarian tumour, and quantities of thick catgut had been used. She thought the case was probably hopeless from the first. She knew that the patient could not have contracted the sheep disease mentioned by Dr. Richardson in his paper, as the patient had come from a part of England in which it was absolutely unknown. The time of the dissolving of the catgut was the time of being infected, and that had made it impossible for her to exonerate the catgut.

Mr. Pearson recounted the clinical history of one of the cases alluded to by Mr. Gunn, in which the patient died about 28 or 30 hours after the onset.

The Secretary said it seemed difficult to get over the fact that in every single case catgut had been used. They knew the source of the catgut and the probability of its being infected, which made the conclusion of its responsibility all the more probable. The extreme virulence of the cases seemed to be at variance with the results of the bacteriological examination. The conditions inside the body were not such as would be expected to favour the growth of the bacillus; in two of the cases there was no suppuration, and therefore no septic organism to prepare the way for the bacillus, and the tissues were well supplied with oxygen, which was also unfavourable to the bacillus.

Mr. Gunn, in reply, said Dr. Richardson had made extensive inquiries as to the methods of sterilisation employed, and had then come to the conclusion that there was no absolutely perfect method.

# WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD JUNE 4TH, 1909.

Mr. Canny Ryall, in opening a discussion on SPINAL ANALGESIA, showed a series of diagrams illustrating the technique

showed a series of diagrams illustrating the technique which he employs at the present day. He now operates on all parts of the body under the influence of this method, and has injected patients who have

had such operations as craniectomies, excision of the sympathetic, extirpation of the larynx, and excision of one half of the tongue, together with removal of the glands from both sides of the neck, performed painlessly and without danger. Children are not exempt, for he has injected a little girl, two and a half years of age, who was submitted to an operation on the head without the slightest alteration in her general condition. He introduced the method of making high injections into Budapest and Vienna. In Vienna he injected an old woman from whom Professor Eiselberg removed the greater part of her thyroid, weighing over 12 oz., with the greatest success. These results are due to Jonnesco's discovery which enabled him to incorporate strychnine with novocain. Novocain is a depressant to the vital centres. Strychnine, on the other hand, is a stimulant. When these drugs are mixed together and injected into the subarachnoid space, the strychnine, by neutralising the depressing effect of novocain, prevents the occurrence of respiratory paralysis. Having described numerous experi-ments which have been carried out, he mentioned that he had given a dog a suboccipital injection containing ao centigrammes of novocain, without death resulting. ao centigrammes of novocain, without death resulting. For operations on the upper part of the body the needle is inserted into the first, and for operations on the lower half, into either the eleventh or twelfth dorsal spaces. He rarely now uses lumbar puncture, for he obtains much better results by giving the injections into the dorsal region of the spinal canal. Although sub-occipital injections have been given by him, he finds no advantage in making a cervical him, he finds no advantage in making a cervical puncture, for perfect analgesia, lasting an hour or longer, can be obtained in the head and neck, by injecting the solution between the first and second dorsal spines. The great danger of spinal analgesia is the likelihood of respiratory paralysis supervening, but now that we know strychnine prevents its occurrence. it should be the duty of everyone employing this method to incorporate this drug with the analgesic solution. He cannot understand why spinal analgesia is not more often used in this country, for in a great number of cases it has many advantages over general anæsthesia.

# FROM OUR SPECIAL CORRESPONDENTS ABROAD.

#### FRANCE,

Paris, June 13th, 1909.

DEPOPULATION OF FRANCE.

TUBERCULOSIS carries off annually 150,000 persons in France. This large mortality might be considerably reduced, affirms Prof. Courmont, by serious prophylactic measures as obtain in England and Germany.

The first step in this direction should be the destruction, as far as possible, of the seed by which the malady is disseminated. Phthisical patients expectorate millions of bacilli daily, and this emission goes on for years, commencing almost always before the patient takes to his bed. Many of these patients lead a normal social life, mixing with healthy persons, and spreading contagion around them. Here isolation is not possible, yet something should be done in view of self-preservation.

The examination of the sputa of all the patients, even the poorest, should be made, and for this purpose laboratories for the diagnosis of the affection should be created in every province. On the other hand, the habit of spitting on the ground or in public vehicles should be suppressed as much as possible, as it constitutes one of the great factors of dissemination. The use of cuspidors should be more general, whether in railway stations, public edifices, or in the sick room.

The precautions to be taken as regards the patients

The precautions to be taken as regards the patients themselves, although necessary, are difficult in their application.

Isolation was proposed, but neither the patient nor his friends would accept it. Notification of tuberculosis is not compulsory in France, contrary to what exists in other countries.

According to Prof. Courmont, it should be rendered obligatory as soon as bacilli are found in the sputa. Compulsory disinfection of the dwelling, of handker-chiefs, cuspidors, should follow the notification.

The question of isolation of the patients in separate wards, pavilions, or hospitals is of great moment. A ministerial circular of 1904 prescribed isolation, but in many hospitals the tuberculous patients are in the common wards, and thus constitute a danger to the other inmates.

Consumption hospitals as existing in England should be created in every region; these sanatoria should be open to patients in every stage of the disease, both curable and incurable.

Certain professions should be looked after and protected. Landouzy proved that washerwomen were particularly affected with tuberculous disease, and this professional malady would be diminished the day when tuberculosis being notified, the infected linen would no longer be mixed with the rest.

Bakers are also very liable to the malady; it is said that one-fourth of the bakers are consumptive! The assertion may be exaggerated, but it is certain that a great many of them fall victims to the disease, and the bread handled by these bakers, constantly coughing, is contaminated to the danger of the public. The only remedy here is the substitution of the mechanical to

the hand troughs.

In order that all these measures should be put into practice, the public mind should be educated by lectures, pamphlets, press articles, instruction in the

schools and the regiments.

The destruction of bacilli of animal origin is of paramount importance. Pork meat when tuberculous is highly dangerous, but in France at least, pork is rarely tuberculous.

Dogs, especially in towns, are more frequently tuber-culous than is believed and propagate the malady. The parrot is very contagious (tuberculosis of the

bill).

Bovine tuberculosis is very common; the meat is sometimes dangerous, the milk very frequently. Clinical diagnosis being almost impossible during a long period of the disease, prophylaxy should be based on the use of tuberculin. If the temperature rises notably within 24 hours after an injection of tuberculin (the old lymph of Koch), the probabilities are that the animal is infected, and should be immediately removed from the stable. removed from the stable.

A very severe control of the dairies should be rendered obligatory, and a law passed permitting an indemnity to the proprietors of the diseased animals. All this will take time, but in the meanwhile, the public should be warned against eating raw meat and drinking unboiled milk.

After considering the seed, a word about the soil is necessary for the conclusion of this study of the most

important question of the future of the race.

As we have seen, the human soil resists the invasion of tuberculosis fairly well, and to increase this chance of resistance several measures should be taken. If tuberculosis is not directly hereditary, the children of tuberculous parents are more or less predisposed to contract the disease; they should consequently be removed from the seat of contagion to the country. Alcoholism predisposes to the malady, and should be denounced urbi and orbi.

Tuberculosis being a malady of the weak, the insufficiently fed, and ill-housed, it should be regarded as a social evil and treated by social remedies.

One of the great producing causes of this malady is insalubrious dwellings, and against which little or nothing is done in France. In England, on the contrary, legislation concerning houses unfit for habitation is very efficient, and London has spent millions during the last thirty years on sanitary improvements in the poor districts of that immense city where tuber-culosis has in consequence notably diminished.

Germany arrives at the same result but by different means. It has created popular sanatoria thanks to its laws on compulsory insurance. By the law of 1883 insurance was rendered obligatory against sickness and accidents, and more recently (1891) against invalidity and old age. Every German workman earning less than £100 a year, is submitted to this obligation; em-

ployers and workmen contribute equally to the insurance fund.

After some years it was perceived that the expenses sickness, invalidity, old age), exceeded the receipts; it was the bankruptcy of compulsory insurance. Instead of resigning to the fatality, the Germans commenced a study of the whole question, with the hope of discovering the causes of the deficit. Tuberculosis was soon found to be the delinquent, and it was decided to take measures against it. Practical people as they are, they decided on creating popular sanatoria, where the workman is treated at the very outset of the disease. By uniting the two insurance funds (sickness and invalidity old-age) over 80 sanatoria were built throughout the country, containing 20,000 beds, with the result that two or three years afterwards, not only were all the building expenses paid, but the receipts exceeded the expenses. In 1902 the reserve fund exceeded twenty million pounds, enabling the administrators to lend two and a half millions for the construction of workmen's dwellings and over eight millions to agricultural industries.

In seven years, the simple fact of interesting them-selves in the struggle against tuberculosis, the German insurance agencies have economised millions of pounds, and this gain represents many human lives. When the workman is ordered to the sanatorium, his

wife and children are supported by the insurance fund.
In France, says M. Courmont, the workman suffering from the disease, works up to his last breath or until he is obliged to go into the hospital and his family is reduced to misery. Without obligatory insurance no prophylaxy of tuberculosis is possible.

# GERMANY. Berlin, June 13th, 1909.

At the last meeting of the Medical Society, Hr. Edwin Pfister gave a demonstration of BILHARZIA DISEASE.

The bilharzia, he said, was a bi-sexual distoma, the exact mode of whose infection of the human system was hitherto uncertain. The males were more powerful than the females, and bore at the extremity a ductus gynæcophorus which wrapped round the female

like a mantle. Hr. Goebel (Breslau) said that the eggs settled in the veins of the pelvis, and were specially numerous in the walls of the bladder and rectum; it was the eggs and not the adult worms that were pathogenous. By means of their spurs they forced their way into the walls of the capillaries, then through them, and were continually pushed forward into the tissues by were continually pushed forward into the tissues by other eggs behind them, so that at last they were capable of filling the bladder walls with infarcts, and becoming calcified. When they were forced into the epithelium they set up a growth, polypi developed, having a hollow space in the centre, and so a cystilize cystica resulted. Even if true new growths were rare, carcinomata certainly developed, which, in the speaker's opinion, were so far in etiological connection with the parasite that the eggs, acting as foreign bodies, set up an atypical growth in the epithelical state of the state thelium. It also happened in rare cases that both ureters and kidneys became diseased; they might block up the ureter and so lead to hydronephrosis; carcinoma of the kidney had also been observed.

Diseases of the intestine and peritoneum were also brought about by the parasite; in the one situation, polypus formation; in the other, pseudo-tuberculosis. The speaker had also seen elephantiasis of the scrotum and perinæum caused by bilharzia, and calculi in which the worms were found. A large number of preparations and projection illustrations

were shown.

Hr. Orth gave an account of a parasite met with and studied in Japan, the schistosomum japonicum. It belonged to the same group as the bilharzia, but it was larger than that one, whilst the eggs were smaller, and carried no spur. These worms also lived in the region of the branches of the portal vein, but passed less frequently into the pelvis, but laid their eggs in the liver, lungs, walls of the intestines, and brain. Giant cells developed round the eggs. The parasite occurred in China and Japan.

Hr. v. Hansemann remarked that the bilharzia was an especial sponger on the epithelium. Although car-cinoma might arise where it settled, it could not be looked upon as a carcinoma parasite in the strict sense of the word.

ÆTIOLOGY OF HYPERTROPHY OF THE PROSTATE. This subject was brought forward by Hr. Rothschild. In a large series of cases in which there was a possible commencement of hypertrophy of the prostate he had made investigations and had drawings made of the parts. The origin of the changes, he claimed, was in periglandular infiltration around the outlet openings, through which these were blocked up; this resulted in retention in larger or smaller sections of the prostate, whereby a compensatory hypertrophy was set up in other parts.

As regarded treatment, a deduction might be drawn

from these facts that the so-called sexual operations, on which for a time such great hopes were centred, as well as the proposed ligature of vessels, were without any object or aim. He thought an intermittent treatment of the chronic prostatitis was rather indicated, in order, if possible, to prevent the formation of cicatrices or masses of connective tissue in the

prostate.

# AUSTRIA. Vienna, June 13th, 1909.

INFANTILE SPINAL PROGRESSIVE ATROPHY. AT the Gesellschaft für Innere Medizin, Popper presented two sisters, æt. 4 and 2 respectively, who seemed to be suffering from the Hoffmann-Werdnig disease, viz., progressive muscular atrophy in the young. According to the mother's story the children were healthy and active when they were born; no apparent weakness about legs or arms. About six months after birth the movements of the legs and arms began to get gradually weaker, commencing in the legs. Through length of time it extended over the legs. Through length of time it extended over the entire body, the limbs becoming quite helpless, and the child being unable to sit up without support. At first, never having learned to walk, the legs remained thick, but soon became emaciated. Their present contains the state of the state o dition may be recorded thus: The elder fairly well nourished for its age, the cranium normal, the brain and cerebral nerves in the same condition. The younger, two years old, was soft and flabby with apparent fatty degeneration of the cellular tissue, so that the muscles of the extremities, which were certainly atrophied, could scarcely be felt. In consequence of the weakness the child could scarcely raise its hand to its mouth. The left arm at the shoulder-joint was quite loose, and could be bent far beyond the normal range; there were no contractions or fibrillary vibratowards the spine, the thorax crushed together and the head had to be held up. The muscles of the shoulders, back and pelvis were distinctly atrophied, while the lower extremities were in the same condition. There was no hypertrophy present, and both feet assumed the equino-varus position. There was no tendon reflex, and degenerative reaction was obtained by the electric current. The sphincters were normal, sensibility undisturbed, and the intelligence active. The elder, a girl, æt. 4, had a similar condition, but from the history it appeared to be more protracted in its approach than in the younger. There were still slight contractions to be obtained in the lower extre-

mities, which were held in the bent position.

These symptoms seemed to agree in every particular with Hoffmann and Werdnig's recorded cases under "Chronic spinal muscular atrophy having a con-genital basis," or what they preferred later to designate "Premature infantile progressive spinal muscular atrophy."

TOXIC COBRA HÆMOLYSIS.

Bauer and Lehndorff gave an account of their experiments with the toxine of the cobra. It may be remembered that Calmette gave the reaction with this toxine as characteristic of the early stage of tuberculosis when no fever or cachexia was present. Their experiments extended over 140 cases, with the serum in both healthy and diseased patients, and are now convinced that the toxine has no specific reaction for tuberculosis, as they only found it present in 47.3 per

cent. On the other hand, they found it more intense in febrile and cachectic phthisis than in the early nonfebrile state. In syphilis, however, they had 50 per cent. of positive results. In the new-born the cobra toxine was absent in the serum, although present in the retro-placental blood of the mother. In cerebrospinal effusions and many other sera, it seemed to have an active antagonistic action. Frankl thought that the maternal serum may account for this differ-ence, as it possesses a large quantity of lecithin, while the child has none, and it has long been recognised that the placenta is richer in lecithin than any other organ of the body. Landsteiner and Halban, only a organ of the body. Landsteiner and manual, only a year ago, proved this difference of serum in mother and child, which is certainly of great serological importance when discussing toxines of this nature. There is another barrier to the similarity in the two hæmatic systems, viz., they contain different lipoid constituents in the circulation.

### HUNGARY.

Budapest, June 12th. 1909.

AT the recent meeting of the Budapest Inter-Hospital Association, Dr. Révész read a paper on HOT SALT SOLUTION FOR ULCERS.

He extols hot physiologic salt solution over all anti-septics. He said these, if strong enough to be bactericidal, must necessarily cause death of tissues already lowered in vitality. The salt solution (9-1,000) used at a temperature of 50° C., has a physiological effect on the tissues promoting phagocytosis, and at the temperature employed is fatal to some bacteria, though not to spores. The ulcer is irrigated with the solution for a quarter of an hour, and a sterilised dressing (gauze, cotton wool, and bandage) is then applied. This is done daily until the ulcer cleans, then as often as necessary. Healing proceeds rapidly, and the method is especially suitable for cases which cannot afford time to lie in bed.

Dr. Sas read a paper on the Permeability of the Intestinal Walls. He said that many experiments on new-born guineapigs have convinced him that the intestinal walls are not permeable by bacteria, with the sole exception of tubercle bacilli. Even if small amounts of the latter are added but once to the food, a tuberculosis will develop, just like in older animals. The infection generally takes place from the mouth and the verminance of the control of the contr form appendix. The bacilli will travel through the walls without causing any loss of continuity, and eventually reach the lymphatic system. On inoculating other animals with the blood and lymphnodes of these guinea-pigs, non-tuberculous nodules developed, which may be an evidence of immunisation. Foreign proteids were not absorbed by the intestinal walls, yet slight amounts of diphtheria and tetanus antitoxin passed through in young, but not in older animals. In rabbits the intestinal walls were found much more permeable towards both bacteria and proteids.

THE INFLUENCE OF X-RAYS ON THE BLOOD. The X-rays seem to have a specific action upon the blood, for the leucocytes rapidly disappear after exposure, says Nemes, in the Orvasok Lapja for May 20th. In small animals, such as mice, the blood may be found completely free after an exposure of several hours, while with larger animals it is much more difficult to destroy all the cells. The destruction goes on chiefly in the circulating blood itself, for at certain Among the different varieties of white cells, the lymphocytes seem to possess the least resistance. Owing to the breaking down of the white cells, a leucotoxin is formed in the serum both within and without the body. It is an interesting fact that if this leucotoxin is injected into other animals, a decrease of the number of leucocytes may be seen soon after. leucotoxin may be rendered inactive by heating up to \$5° to \$60° C., it passes from the mother to the fœtus by way of the placenta, and it will eventually produce an immunity against itself. The cause of death after exposure is only rarely to be ascribed to infection resulting from dermatitis; in the majority of cases an intense nephritis must be held responsible. The hæmoglobin, red blood cells, and the blood platelets

are only slightly affected by the Röntgen rays. Two Germans, Linser and Helber, have carried on similar experiments with radium and with ultra-violet light, but an effect upon the blood was never detected. It seems that these rays do not possess the power to penetrate the tissues to the same extent as the Röntgen rays.

Pernicious Vomiting.

At the Medical Society, Dr. Sebestyéa said that for the milder cases of pernicious vomiting the usual remedies must be tried. The intestinal tract should be thoroughly cleansed, and large injections of water may be given, and the stomach washed out. If the vomiting persists, however, it takes on the pernicious form, and then the only thing that will end it is the determination of the pregnancy. For this the rapid dilatation of the cervix and the emptying of the uterus has been the most advised means, but there are beginning to be doubts about its applicability in some of the severest cases where the symptoms have affected the general health very much. The shock of the operation may of itself kill the patient. The administration of an anæsthetic adds to the danger, and if chloroform is given the toxic process within the body seems to be intensified. All the portions of the fœtus and its adnexa must be removed, or the vomiting will continue. He referred to a case of Dr. Stone's, of New York, in which a small portion of placenta was left, with failure to relieve symptoms. When this was removed the vomiting stopped.

# FROM OUR SPECIAL CORRESPONDENTS AT HOME.

#### SCOTLAND.

MEDICAL INSPECTION OF SCHOOL CHILDREN IN MIDLOTHIAN.—The Education Committee have made a series of recommendations on this subject, briefly as follows:—The inspection of school children is to be placed under the general direction of the county medical officer of health, with the assistance of such other specially appointed medical officers as may be required. The duties of the chief medical officer are to consist of direction and organisation of the work of his subordinates, transmission of all reports on sanitation or infectious disease reaching him to the public health officer; the duties of the junior medical officers are to report on sanitation of school premises, on infectious disease, and on the results of their inspection of school children. They are also to urge parents to procure medical advice for their children when this seems required, and to report failure to comply to the School Board concerned. They may be required to report to the Board on cases in which illness is alleged as an excuse for irregular school attendance.

EDINBURGH ROYAL INFIRMARY.—The medical outpatient department, which has long been in a very unsatisfactory condition as regards its premises, has been remodelled during the past year. There has now been provided a large waiting-room, with proper isolation rooms for suspected cases of infection, and with dressing rooms and lavatory accommodation. These dressing rooms communicate with a large demonstration room with raised benches, to accommodate eighty students, for whom a separate entrance is provided. Private rooms for the physicians on duty, and a dark room for the examination of the eye have also been provided, and the department is so planned that patients leave the building by a special exit, without returning through the waiting-room. In passing it may be remarked that in the Royal Infirmary it has never been the practice to supply medicine, but only to give advice, to out-patients. The whole department is on thoroughly modern lines; there is special accommodation for the nursing staff, and all the fittings and furnishings are thoroughly up-to-date. The cost of the department has been about £3,000;

The Cost of the department has been about 25,000, the architect is Mr. A. Balfour Paul.

The Budget and Alcoholic Drugs.—At the meeting of the directors of the Edinburgh Royal Infirmary on the 31st ult. the adverse effect of the

new spirit duties on the finances of the Infirmary was considered. Dr. Mackenzie Johnstone submitted a statement based on last year's figures, showing that the increased cost of alcohol would affect the institution to the extent of £112. This does not apply to alcohol as a beverage, but to the preparations in which alcohol is largely used; anæsthetics alone mean an increase of nearly £50. A letter was read from Dundee Infirmary asking support to get some concession in regard to the making of tincture and other pharmaceutical preparations. The result of the tax is really an increased expenditure on drugs amounting to nearly 10 per cent.

ROYAL COLLEGE OF PHYSICIANS' LABORATORY.—
The Laboratory Committee has recently issued new regulations concerning the reporting on specimens. Hitherto such reports have been issued gratuitously to all and sundry medical men, and a good many years ago the City paid the Laboratory several hundreds annually for its reporting work. When the Usher Institute was opened the City reporting work was transferred to it, but a great many practitioners continued to send their specimens to the College Laboratory, which in its turn, went on giving gratuitous reports. The reporting, however, had to be kept in check in some way or another, and in the future a scale of charges, not differing materially from those in vogue elsewhere, will be made to practitioners who are not Fellows or Members of the Royal College.

REGISTRATION OF NURSES IN SCOTLAND.—The

following resolution has been forwarded to the Prime Minister:-The Executive Committee of the Association for the Registration of Nurses in Scotland, at a meeting held in Edinburgh on May 14th, expressed their satisfaction that the Prime Minister was unable to assent to the proposals of the deputation which waited on him on the 13th inst. This Association (which represents public opinion and, with a few exceptions, the opinions of the medical and nursing profession in Scotland) trusts that it will be afforded an opportunity of placing its views before any committee of the House of Commons that may be appointed to deal with that important subject. The statement (already published in the Medical Press) gives in detail the reasons of the Association for objecting to Registration Bills No. 1 and No. 2, and although Scotland does not desire to be associated with the scheme of either of these Bills, the Scottish committee see no reason why a Bill should not be introduced which would be satisfactory to England, Scotland and Ireland, arranging for Representation Branch Councils, and for a separate register for each country. to be embodied in one common register, the branch councils to supervise examinations in their own country, just as is done under the Medical Act (1858) and its subsequent amending Acts. The views held by this Association coincide generally with the recommendations of the Select Committee which reported to Parliament in 1905 on the question of the State Registration of Nurses.

#### BELFAST.

"Interesting Meetings" in County Down.—Much interest has been aroused in medical circles by a series of meetings held this week in the northern parts of County Down, all of them addressed by Dr. Henry O'Neill. The daily papers, evidently rather at a loss how to ticket them, put them under the heading of "Interesting Meetings." They are supposed to be in furtherance of a plan to obtain more labourers' cottages, but many other questions are discussed, and though party politics do not seem to be alluded to, there is an idea abroad that these meetings are stepping-stones on the road to Westminster, towards which that original and energetic surgeon set his face when a few years ago he qualified as a barrister. In Portaferry, for instance, Dr. O'Neill dealt not only with the question of labourers' cottages, but also with the need for better quay accommodation, the need for more lighthouses on the coast, the necessity for a technical school, and the medical inspection

of school children. On the last subject he made the rather startling remark that Ireland was the only country in Europe where school children received no periodical medical supervision

country in Europe where school children received no periodical medical supervision.

Belfast Board of Guardians.—At the annual meeting of the Belfast Board of Guardians, held last week, Dr. J. S. Bryars was unanimously re-elected chairman. During the past year, his first in office, he has won the respect of all parties by his fairness and courtesy in dealing with a sometimes unruly board, and his re-election is a very real compliment.

Expenses of the Belfast Health Commission.—

EXPENSES OF THE BELFAST HEALTH COMMISSION.—An interesting discussion took place at a special meeting of the Corporation last week, when the question of the payment of the Corporation's share of the expenses of the late Belfast Health Commission came up for settlement. It appears that counsel's opinion had been taken, and was to the effect that they were not liable for the expense of the three English members of the Commission, and many members of the Corporation wished to refuse payment. The Earl of Shaftesbury, in a most sensible speech, moved that the payment should be made, sooner than litigation started which might land them in far heavier expenses, and specially as they admitted that they had got good value for the money. After a lively discussion the motion was carried by 17 votes to 9.

Tuberculosis in County Down.—At the annual

TUBERCULOSIS IN COUNTY DOWN.—At the annual meeting of the Down County Council, held last week, the chairman, the Rt. Hon. Thomas Andrews, referred at length to the question of tuberculosis. The county had, he said, made great progress in many directions, such as the provision of labourers' dwellings, technical schools, workhouse and asylum accommodation, etc., but one great blot remained on it, and that was the presence of tuberculosis, over 5,000 cases in the country causing 500 deaths each year. He had no cut-and-dry scheme to bring before them, but he wished them to turn their minds to this great problem.

### LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

#### THE PRESS AND THE EMPIRE.

To the Editor of The Medical Press and Circular. Sir,—Before me is one of the leading papers of the day; I need not say whether Lendon or provincial. It contains a report of the second sitting of the Press Conference, the subject for discussion being "The Press and the Empire." Many noble sentiments, and aspirations by distinguished statesmen, with much laudation of that noble institution the Press of the Empire, are reported. Occupying nearly a full page opposite the report there is printed, as an editorial article, a fulsome puff of a grotesque system of quackery. This puff may have cost any sum between £100 and £250. In other parts of the same paper are other quack advertisements representing at least another £200. At a very mederate estimate the annual income of this great organ, from a traffic which is not only fraudulent, but cruel and deadly, must amount to not less than £30,000. This same paper gives place on occasion to a great variety of financial advertisements which to the eye of an astute City editor display the word fraud in large letters across their face. It is possible the proprietors are quite ignorant of the nature of the enterprises they are thus abetting. Some papers reject advertisements of the kind I refer to; some admit them innocently, and some perhaps in putting them in can be charged with nothing worse than carelessness; but there can be no doubt that the papers, nearly all of which now augment their income from these foul sources, are in most cases well aware of what they are doing. Medical quackery of the coarsely fraudulent kind, especially the traffic in nostrums and sham apparatus, has been more than sufficiently exposed during late years in the medical papers alone, and in a fashion which makes it impossible for any well informed newspaper proprietor to affect ignorance of its

character. The Australian Royal Commission has again done enough to provide enlightenment, whilst cases in the law courts of every grade have further furnished more than sufficient evidence during many years. Leading articles in the foremost papers of the day taking part in this exposure were formerly common: and, strange as it seems, quite lately editorials of this kind have appeared denouncing various forms of quackery, whilst fraudulent advertisements of every kind have been appearing in the same pages. It seems desirable to free one's mind from cant in considering the trade of journalism. If many newspaper proprietors are capable for a consideration of deliberately betraying the simple and suffering public into the hands of cynical knavery there seems no depth of degradation to which under similar temptation they may not be capable of sinking. Why should they not for pay enrol themselves in the ranks of the reptile press subsidised by a foreign statesman, and take part in betraying their country into the hands of its enemies. Baseness equal to this was charged against a great section of the United States Press by ex-President Roosevelt in a speech a few months ago; and the morals of entirely unscrupulous money-grubbers in this country are not likely to be superior to those of their brethren across the Atlantic.

1 am, Sir, yours truly, HENRY SEWILL.

The Old Rosery, Redhill, June 9th, 1909.

#### "THE CHURCH AND HEALING."

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your comments on above subject in last issue are much to the point, "A certain section of the Church is being drawn towards Christian Science, falsely so-called." The wonderful "cures"(?) said to be effected by this agency we must charitably suppose are explained by "terminological inexactitudes," or the neurotic element in the person acted upon. The new treatment by prayer and poultice (simultaneously applied, we presume) should soon produce astounding effects, the difficulty being which treatment to attribute the "cure" to. Will payment be made by results? As the Christian Scientists, from their apostle, Mrs. Eddy, downwards, manage to make it pay, so different from the advice given by the Master (Matthew x., 8, 9, 10): "Heal the sick—freely ye have received, freely give." Mrs. Eddy, at any rate, has made a good thing out of Christian Science, while posing as a second "Eddy" stone lighthouse, with her "Edifying" handbook, "A Key to the Scriptures," supposed to throw light on the Sacred Volume.

I am, Sir, yours truly,
ALEXANDER DUKE.

London, W., June 10th, 1909.

AN URGENT APPEAL FOR ASSISTANCE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—May I ask you courteously to publish a further list of donations in answer to the "appeal" which you kindly inserted in THE MEDICAL PRESS AND CIRCULAR for May 19th, 1909?

I am, Sir, yours truly,

### OBITUARY.

#### WILLIAM HAMPDEN BRODIE, M.D.ABERD.

We regret to announce that the death has occurred, near Johannesburg, of Dr. William Hampden Brodie, a medical practitioner well-known on the Rand, where he was highly esteemed. Dr. Brodie graduated at Aberdeen University in 1880. He afterwards visited America, and subsequently proceeding to Johannesburg in the early days, he took an active part in the work of the Reform Committee, holding as he did strong sympathies with that movement. He served during the South African war as Medical Officer on the hospital ship, Lismore Castle, and No. 6 General Hospital, Johannesburg. He had also been Medical Officer of the W.N.L.A., and of the Ferreira Group of mines, and till recently had been acting as Medical Adviser to the Central Administration. The cause of death was pneumonia, with which Dr. Brodie was struck down only a few days before his death.

HENRY JOHN HUNT, M.R.C.S., L.R.C.P., J.P.

WE regret to announce that Henry John Hunt, a well-known Harrogate medical practitioner, has died in London at the age of sixty-eight. He was a member of the Royal College of Surgeons, and a Licentiate of the Royal College of Physicians, and had held the appointment of Surgeon to the Harrogate Bath Hospital. Mr. Hunt was a magistrate for the West Riding of Yorkshire.

HENRY KAY RAMSDEN, M.B., CH.B.VICT. WE regret to announce that Dr. Henry Kay Ramsden, of Chelsea, has died after a long illness at the age of forty-two. He took the M.B., Ch.B. degrees at Victoria University in 1891, and held various appointments, including those of House Surgeon at the Central London Throat, Nose, and Ear Hospital, Clinical Assistant at the Royal London Ophthalmic Hospital and Central London Ophthalmic Hospital, and Surgeon to the Town Hospital, Guernsey and the General Hospital, Chillagoe, Queensland. He had also been a civil surgeon with the South African Field Force, and was a Surgeon Captain in the 6th London Riffes.

# MILITARY & NAVAL MEDICAL NOTES.

It is notified by the War Office that a new regimental march has been approved for the Royal Army Medical Corps. The writer recollects well the time when a band was absolutely refused by the authorities for the Corps when permission was asked to organise it. But that was a time of deep jealousies and antiquated views of the "stay-where-you-are" school! The minds of men in power now have expanded; they move with the times, and adapt themselves to environment.

An American Army medical officer representing the United States, who was studying our system at Aldershot, expressed the view to the writer that the R.A.M.C. should have colours. That may come later. But, festina lente.

THE Government of Mysore (India) have recorded their appreciation of the ability with which Lieut.-Col. J. Smyth, Indian Medical Service, has discharged the duties entrusted to him during his deputation to study the system of sanitation in Japan. Government observes that most of the methods adopted in Japan are purely European, and inapplicable to Indian conditions. Government have decided on granting an extension of Lieut.-Col. Smyth's service in Mysore for five years, and negotiations are passing between the Mysore and Indian Governments on this proposal.

An order has been received at the dockyards that, in view of the attendant risk to health, no virus or poison should be used in future for the extermination of rats without the prior concurrence of the responsible Medical Officer of the Dockyard.

THE position of the Royal Naval Volunteer Reserve is alluded to by a correspondent of the Times (June 41, who says of the medical officers that there are at present 30 thoroughly qualified surgeons. They form a small but a valuable reserve for the Navy. They are enabled to acquire experience in work of a specially Naval character by being attached for short courses of instruction in a Naval hospital and on H.M.'s ships, receiving at such time the pay of their rank. If they are certified by the Medical Director-General of the Navy as having taken full advantage of the instruction, extra capitation grants are allowed for them. It is greatly to be hoped that this most useful branch of the Reserve may be increased numerically.

In a health point of view the relative values of coffee and tea for soldiers is worthy of attention. Dr. Huchard, of the Necker Hospital, and a member of the Paris Academy of Medicine, considers that the decision to replace coffee by tea in the German Army will be a good thing—for the enemies of Germany. He thinks that the experiment, besides being a waste of money (since the authorities will be obliged to return to coffee—why, he does not say) will have serious consequences for the health of the soldiers. He says that either the soldiers will be given only a small quantity of tea, in which case they will derive no nourishment, or they will be given a lot of tea. and with it cardiac trouble.

THE insanitary state of quarters for married soldiers owing to overcrowding is receiving much publicity, and it is to be feared that, in consequence, much harm accrues to the Army. There can be no doubt that many of these quarters would not be passed as fit for residence under the inspection of officers of health in civil life. No fault whatever for this lies with the Army Medical Service, who are absolutely disheartened at their repeated reports and recommendations bend pigeon-holed and being met by the authorities with a non possumus and "We have no money—."

The Leeds Army Medical Corps—i.e., the 1st and 2nd West Riding Field Ambulances R.A.M.C., are spending some time under canvas at Alwoodley, a stretch of country outside Leeds. They are over 250 strong, and marched out with full medical accountement, operation tent etc. There were 40 horses and three ambulances. The Military Mail says:—The corps presented a smart and soldierly appearance as they passed through the city under the command of Lieut.-Col. A. E. L. Wear." Attached to the unit is a transport company and the 2nd Northern General Hospital Staff of the R.A.M.C. School of Instruction.

DR. SEYMOUR STRITCH, Governor of the Apothecaries' Hall, Dublin, has been presented by the directors of the Apothecaries' Hall with a piece of plate on the occasion of his marriage.

#### The Harben Lectures for 1909.

THESE lectures will be delivered by Prof. R. Pfeiffer. M.D., Breslau, in the Lecture Room of the Royal Institute, on Monday, June 21st, Wednesday, June 23rd, and Friday, June 25th, at 6 p.m.

## The Cavendish Lecture for 1969.

SIR VICTOR HORSLEY, F.R.S., will deliver the Cavendish Lecture before the West London Medico-Chirurgical Society on Friday, June 25th, at 8 p.m. in the Kensington Town Hall. Subject, "The Cerebellum."

# REVIEWS OF BOOKS.

# AIDS TO FORENSIC MEDICINE AND TOXICOLOGY. (a)

APART from the desirability of calling attention to a new edition, a review of this book is almost super-fluous. When six editions have been voraciously devoured by students, a book may truly be considered acceptable. The reasons for its popularity may be many, but probably the chief is the way in which the subject-matter is treated. A student with an already surfeited mind will turn with relief to a book where information is presented in a manner reminiscent of the "Comic Blackstone." The author is a humorist, but he also appreciates the delicacy of certain portions of his subjects. His knowledge of human nature is great, and, with a keen savoir faire of his subject, makes the book both eminently readable and useful.

A great deal of new material has been added, especially in Part I. ("Forensic Medicine"), and abstracts of most of the new Acts bearing on the subject are given. In the toxicological part we notice the inclusion of synthetical coal-tar products such as the analgesics so popularly used and abused. We may note that the author does a little injustice to the tests for lead in water when he says that one-tenth of a grain of lead per gallon can be detected. It is sometimes necessary to detect and estimate a fifth of this quantity.

# PATHOLOGY AND TREATMENT OF DIABETES. (b)

In these three lectures Dr. Pavy gives a lucid exposition of his ideas concerning the ætiology of diabetes. He begins by attacking in no uncertain way the most He begins by attacking in no uncertain way the most generally accepted among the old views of carbo-hydrate metabolism, known as the "glycogenic theory." He points out that, as part of this theory, it was considered that sugar travelled free in the blood from the intestine to the liver, and that the liver was loaded with sugar. The blood in the henatic vains was bewith sugar. The blood in the hepatic veins was believed to contain more sugar than that in the portal system, and the systemic veins were said to be poorer in sugar than the arteries. All this had now been disproved. Sugar is normally present in the urine, in quantities too small to be detected by Fehling's solution, but proportional in amount to that in the blood. This contention could be proved by intravenous injection of sugar when it immediately appeared in the urine. On the other hand, ingestion of large quantities of experience in health median of large quantities of carbohydrate in health made no difference to the amount of sugar in the urine, so that it was inconceivable that it had obtained entrance to the blood in the form of sugar. The view that the liver was a powerful means of preventing sugar absorbed from the intestine from gaining access to the general circulation was disproved by Eck's fistula operation, for by this the liver was cut out of the

circulation, yet no glycosuria resulted.

Everything, he thinks, points to the disappearance of sugar at the seat of absorption, and for this he has a very ingenious explanation. After referring to the recent work, which has shown that carbohydrates may be transformed into proteid by the synthetic power inherently belonging to bioplasm, he points to the large number of lymphocytes in the absorbent area. These, he considers, furnish the active bioplasmic growth, which assimilates the sugar absorbed from the intestine, and carries it in the form of a large and complex protein molecule. It is thus locked up, and does not run off in the urine, as it assuredly would

do if it circulated as sugar. According to the author, the next step is one of autolysis of the lymphocytes, and in this process of melting down the protein that has been generated within them passes into a state of solution under the form of the albumin, globulin, and fibrinogen appertaining to the plasma. This is utilised by the tissues through the agency of a fermentlike material out of the body fluid. Looked at in this way, the tissues draw their nutrient supply from the material elaborated from the digestive products at the seat of absorption, instead of the digestive products being conveyed as such through the circulating system to the tissues.

To the liver he ascribes the function of storing the excess of carbohydrate in the form of glycogen. believes that with exercise a demand for sugar arises, which exhausts that in the blood, and so more is caught on from the liver. To supply this the glycogen is converted by enzyme action into sugar, which is combined with a protein molecule in the blood. He adduces evidence to favour the view that the pancreas acts by supplying a body which, in the language of immunity, performs the part of an amboceptor to link up the carbohydrate to the bioplasmic molecule, i.e., to the lymphocyte at the seat of absorption, and suggests that it may act similarly in the transformation of sugar to glycogen in the liver.

Dr. Pavy's position as an authority on diabetes is so great, and justly so, that these lectures could scarcely fail to be food for much thought, and may be said to constitute the last word on the subject. If one ventured a criticism, it would be that the theory he advances is of itself so complex and intangible, voking, as it does, the aid of various hypothetical enzymes, that, although eminently reasonable, it is at present beyond proof or disproof.

#### THE BONE MARROW. (a)

This handsome volume represents the results of Dr. Dickson's work during his tenure of the Crichton Research Scholarship in the University of Edinburgh, to which University it was afterwards submitted as a theses for the M.D. degree. The scope of the volume is sufficiently indicated by the title; it is in the main a description of the cells met with in the marrow in health and discourse and activation. health and disease, and a study of some of the reactions of that tissue. It is thus a really valuable introductory treatise, which will serve as a basis for further work, and will prove of great assistance to all engaged in the study of this most difficult structure. Dr. Dickson is less concerned with attempts to throw light on the causes of the phenomena he describeson the nature of chemiotaxis, for example—than with a description of the changes themselves. One of the chief problems in the cytology of the blood is the relationship of the various forms of leucocyte. The view adopted in the text is one now very generally held, viz., that the large non-granular basophile mononuclear is the source of the whole neutrophile series, and that it is itself probably derived from a smaller cell of similar character—the "undifferentiated lymphoid cell" (Wolff). The eosinophile and basophile series The eosinophile and basophile series are regarded by Dr. Dickson as totally distinct from the neutrophile series, and no definite opinion is expressed as to their origin. In discussing another vexed question, namely, the manner in which ervthroblasts lose their nuclei, Dr. Dickson leans to the view that the process is not one of extension, but of karyorrhexis or karyolysis. One of the principal features of the book is the wealth and beauty of the illustrations. The plates, particularly those showing the naked eye appearances of the marrow in health and disease, are alone sufficient to ensure its having permanent value. Although Dr. Dickson has not in this thesis made any revolutionary observations, his is a painstaking piece of work which will form a secure foundation for further research, and is a large mass of solid information on a very difficult subject.

ST. BARTHOLOMEW'S HOSPITAL REPORTS. (a)

THE new volume of the "St. Bartholomew's Hospital Reports " quite maintains the high reputation which the reports of this hospital have gained for themselves in past years, and reflects the greatest credit on its The volume before us contains some nineteen papers dealing with medical and surgical subjects, as well as the statistical tables dealing with the work of the hospital for the past year. Some of these papers are of guite unusual interest, such as that contributed by Dr. Herringham on "Gastric Ulcer and Gastro-Stasis." In this paper the author deals with the cases of gastric ulcer that have occurred in the hospital during the years 1887-1906. Dr. Cane gives an interesting analysis of 1,196 midwifery cases attended during the twelve months in the Extern Midwifery Department. In estimating the morbidity, Dr. Cane adopts the standard in use in Queen Charlotte's Hospital. By this standard every case is considered morbid in which the temperature rises above 100° F., whether the rise is accompanied or not by an increase in the pulse rate. According to this standard the percentage of morbidity among the 1,196 patients delivered was 14.3. The corresponding figures for Queen Charlotte's Hospital were 20.0 for 1,642 patients. We must congratulate Mr. Colt, the Senior Resident Anæthetist, on the much fuller report on anæsthetics which appears in this year's volume. In our notice of last year's reports we suggested this improvement, and we consider it a distinct addition to the volume for this year. We should have liked, however, a little fuller details of the fatal cases. The explanation of the third of these cases does not appear very clear from the information afforded us.

# ANATOMIE UND MECHANISMUS DER SKOLIOSE. (b)

This volume gives a very complete account of the anatomy of scoliosis. It is bound in an unusual method. The text occupies only a comparatively small bulk, the remainder being taken up by an atlas fitting in a separate pocket of the binding. This has the advantage of allowing the plates to be studied while reading the text without continually turning over the pages.

A good account is given of the alterations in shape and relations of the scollotic vertebræ, with their processes and ligaments, in the adult, and the same conditions are studied in the child. The changes found in other organs—liver, lungs, diaphragm, etc.—are accurately described. The chapters dealing with the minute structure of the bones and the mechanism of the scoliotic change are perhaps the most interesting. It is shown that on the concavity of the curve the bony lamellæ lie closer together, and are thicker than normal, those on the convexity being more open and delicate. The theories attributing this condition, on the one hand, to a mechanical compression and expansion directly due to the torsion, and, on the other, to a laying down and absorption of the lamellæ from the increased and diminished pressures on the opposite sides, are considered at some length.

The plates illustrate clearly and well the matter dealt with in the text. The book can be recommended to any who wish to study the anatomy of scoliosis in detail, and are conversant with the language in which

### PHYSICAL DIAGNOSIS. (c)

THE author has written a book which deals with the physical signs and diagnosis of diseases of the thoracic and abdominal organs. It is divided into seven sections. The first concerns general methods of examination, the second examination of the thorax,

(a) "St. Bartholomews Hospital Reports." Edited by H. Morley Fletcher, M.D., and W. McAdam Eccles, M.S., F.R.C.S. Vol. XLVI. Octavo. Pp. xviii, 287 and 190, 17 illustrations. London: Smith, Elder and Co. 1809.

(b) "Anatomic und Machanian."

the third and fourth examination of the bronchopulmonary system and mediastinum. Sections five and six are devoted to the examination of the cardio-vascular system and the physical signs of its diseases, and section seven to the abdomen. Its scope does not include diseases of the nervous or urinary systems, nor of the blood. As a record of the many physical signs which have been described, in association with abnormalities of the chest and abdomen, we think Dr. Da Costa's book may be said to be exhaustive, but it Da Costa's book may be said to be exhaustive, but it would have been advantageous to emphasise more forcibly those on which greatest reliance can be placed even at the risk of omitting the less important. But the feature which gives this work its greatest value is the author's scheme to correlate physical signs with clinical pathology. With this object in view, he first describes and explains the mechanism underlying the physical signs which may be obtained in the lying the physical signs, which may be obtained in the normal organ and then in the various morbid condi-tions of that organ. Each disease is then considered tions of that organ. Each disease is then considered separately. First, its morbid anatomy is described, then the physical signs which necessarily result, and finally the diagnosis. With so important a lesson to teach, it is a pity that the main issues are sometimes crowded out of their due position by minor points. The argument from pathological cause to physical effect is considerably helped by many good pictures of directly argument and other available illustrations. of diseased organs, and other excellent illustrations and diagrams are plentifully distributed through the book. We think, however, that the model studies do not seem in place in a scientific text-book.

#### GENERAL AND SPECIAL PATHOLOGY. (a)

It is with confidence and with a sense of pleasurable anticipation that one opens a book on pathology by two such distinguished exponents of the science as Drs. Dickson and Beattie, and in every respect is the confidence justified.

In these two volumes the authors have endeavoured

to supply an up-to-date knowledge of pathology, both general and special, which the advances of the last few years have rendered necessary. Great care has been bestowed in making the work full and ample, and the writings of the best authorities have been consulted and quoted whenever necessary, and the authors have succeeded in making their own views clear and distinct. The chapter dealing with the "cell" is one of the best we have ever read.

The illustrations are most excellent. After having read through the work most carefully we offer the joint authors our best thanks for their accurate scholarship, clear exposition, and literary taste.

### LITERARY NOTES.

Dr. METCHNIKOFF'S "Notes on Soured Milk and Other Methods of Administering Selected Lactic Germs in Intestinal Bacterio-Therapy," have been reprinted in pamphlet form of 20 pages by Messrs. John Bale and Co., Ltd. The author's remarks on curdled milk and the action of lactic fermentation in preventing butyric fermentation and putrefaction, and the con-sequent reduction of the sulpho-conjugate ethers in the urine is herein shown. As a means to this end the author suggests the advantage of introducing the living germs rather than lactic acid. He deals with the use of soured milk by races where longevity is common. and then with the virtues and shortcomings of Kephir and Yahourth. The author's opinion on this form of bacterio-therapy is summed up in the phrase: -1 hasten to repudiate the idea that these microbes possess the property of determining longevity or of averting old age, except in so far as they make for a high standard of health."

WOODHALL SPA is so well-known to the readers of this journal that further reference to its resources from a medical point of view would appear almost super-

(a) "A Test-Book of General and Special Pathology." By Dra. Martin Beattle and Carnegie Dickson. Pp. 556, 191 illustration, Rebman, Ltd.

Elder and Co. 1908.

(b) "Anatomie und Mechanismus der Skoliose." Von Woh. Dr. Carl Nicoladoni O.O., Professor der Chirurgie ander Universität Graz. K & Hofrat. Mit 54 Figuren auf 37 Tafelm und dem Portrat des Verfassers. Urban and Schwarzenberg, Wien, Berlin, N. Freidrichstrasse, 1865. Maximillianstrasse. 1909.

fluous. A new handbook and guide to this "Salzo-Maggiore of England," however, is now before us, brought up-to-date, showing that many improvements have been made in the Spa baths, which have been considerably enlarged, and new rooms for the Aix and Vichy systems of douche massage built. Dr. Lionel Calthrop is still medical superintendent at the Spa, an assurance that patients sent there will receive scientific treatment.

# MEDICAL NEWS IN BRIEF

#### Medical Golf.

THE Ulster Medical Association has arranged to present to the British Medical Association a cup to the known as the "Belfast Cup," to be played for at annual meetings and to be won outright by any member winning it three times. It will be first played for on the Friday of the Belfast meeting, on the links of the County Down Club at Newcastle. The cup is designed after the well-known Ardagh Cup. It will be of silver and about nine inches high.

#### Case of Leprosy at Cardiff.

At the Cardiff Seaman's Hospital, on June 1st, one of the out-patients, a Chinaman, lodging in a seaman's boarding-house, was found to be suffering from leprosy. The man was at once admitted to the hospital, and completely isolated, and every precaution has been taken to prevent contagion. The Medical Superintendent is of opinion that the disease was originally contracted in China, prior to the departure of the patient from Hong-Kong two years ago, when he sailed for Europe on a British ship.

#### The Red Cross Society and the Territorial Scheme.

Mrs. C. Davies Gilbert, Vice-President of the District Branch of the British Red Cross Society, gave an "At Home" at Eastbourne, at which Sir Frederick Treves was present. Sir Frederick Treves, in explaining the aims of the society, said an extensive movement, which was not yet completely developed, was proposed for the Territorial Army. The War Office was about to issue within 10 or 14 days a memorandum of what they hoped the Red Cross Society would do in the Territorial scheme, and that under the idea—an idea we never would allow to enter our minds—that the country might be invaded. There were some who thought, however—and their opinion was worth heeding, too—that we might be in error in too strongly insisting on that fact.

#### Medical Golfing Society.

WE are asked to announce that the annual tournament of the Medical Golfing Society will be held at Burnham Beeches Golf Club on Thursday, June 24th. Play will be 18 holes match play v. Bogey under handicap. There will be three prizes in each division—handicap 12 and under, and handicap over 12. The "Henry Morris" Challenge Cup and the Medical Golfing Society's Gold Medal will be competed for. There will also be a Foursomes sweepstake in the afternoon. Any person on the Medical or Dental Registers can join on payment of the annual subscription (4s.), which includes entrance to the tournament. Entries, accompanied by subscription and giving lowest handicap, should be sent to Dr. L. Eliot Creasy, 36 Weymouth Street, London, W., on or before Monday, June 21st. Conveyances will meet trains at Burnham Beeches Station (G.W.R.). Cards may be handed in till 8.30 p.m.

## The Irish Medical Benevolent Fund Society.

The annual meeting of this Society was held during the past week. The President of the Royal College of Physicians occupied the chair. The report of the committee stated that the total amount of the grants recommended since the last distribution is  $\int 1.327$ . The total number of applications considered during the year was 90. Of these 81 were from the widows of medical men, 5 from, or on behalf of, their orphans, and 4 from medical men themselves. The number of appli-

cants this year has been very large, and the amount given in grants has strained the resources of the Society, yet to many of the recipients the aid given has fallen very far short of their claims, and of their urgent necessities. The amount received through the central treasurer was £226 3s. 6d., as compared with £195 the year before. The subscriptions received from branch treasurers amounted to £315 16s. 2d., as compared with £351 1rs. 3d. the year before. The Belfast and Co. Antrim Branch contributed £151 5s., including £5 5s. received too late for audit the previous year. Since the accounts were closed a further sum of £9 13s. 6d. had been received from county branches, £136 16s. 2d. received from county branches, £138 18s. 2d. should have appeared in last year's account, but was not received until that account had been closed. The branch treasurers doubtless do what they can to send their collections in time for audit. At present it is impossible to present the accounts in such a form as to make it easy to compare one financial year with another.

The President of the Royal College of Surgeons moved, and Dr. Cosgrave seconded, the adoption of the report. The former said that out of some 3,000 members of the profession in Ireland there were only 500 contributors to the fund. There was a falling-off in subscriptions, and he thought that one reason for this was that medical men did not know of the existence of the Society and of the work it was doing.

Amongst the other speakers were Dr. Hastings Tweedy, Sir Lambert Ormsby, Dr. J. Magee Finny, Dr. Garland, Dr. Knox Denham, and the Chairman, who pleaded for liberal support of the Society.

# International Congress of Nurses and Nursing Exhibition.

Just ten years ago there was founded in London the International Council of Nurses, which sought to band together the nurses of all nations in a confederation of workers, to further the efficient care of the sick, and to secure the honour and the interests of the nursing profession. On July 19th next this Council will meet at the Caxton Hall, Westminster, to report progress, which, indeed, has been phenomenal, and to receive reports from almost every civilised country upon questions relating to the welfare of the sick and of the nursing profession. A strong contingent is expected from Sweden, and Canada, the United States, Holland, Finland, and Denmark will also be represented. Following the business meeting of the International Council, an International Congress of Nurses, and Nursing Exhibition, organised by the hostess Council of this country, will be held at the Caxton Hall on July 20th, 21st, 22nd, and 23rd. Another interesting session will be that presided over by Lord Sandhurst, Treasurer of St. Bartholomew's Hospital, when "The Relations of Nursing and Medicine" will be discussed. A special feature of the Nursing Exhibition will be the sections organised entirely by nurses, and illustrative of their work. All information respecting the Congress can be obtained from the Secretary, International Congress of Nurses, 431 Oxford Street, London.

# Action Against the Incorporated Dental Hospital of Ireland.

A CASE of considerable interest to the dental profession in Ireland made its first appearance in Court on Friday last in Dublin, when, in the case of "Keogh v. the Incorporated Dental Hospital of Ireland." counsel applied on behalf of the defendants for an order directing the plaintiff, Mr. Myles Keogh, dental student, to furnish the defendants full particulars of the publication of the alleged libel for which the action was brought. It appeared that last year the plaintiff applied for permission to attend the lectures at the hospital as a student, forwarding the fees, and the application was refused, the registrar writing to the plaintiff on October 20th to that effect. The alleged libel was embodied in the following resolution passed by the defendants, on May 18th, 1908:—"Resolved that Mr. Keogh cannot be accepted as a student at this hospital, the Committee having the right by their by-laws to refuse any student without assigning a cause." The plaintiff alleged that these words

would be understood by those having a knowledge of the practice of admission to the dental profession in Ireland to mean that he was unfit, unworthy, and not a proper person to attend the lectures. It was stated on affidavit on behalf of the defendants, that if there was any publication it was to persons interested.

The Court reserved judgment.

#### The Registration of Nurses.

An important meeting of the Irish Nurses' Associa-tion was held last week to consider the steps to be now before Parliament. Miss Huxley, who presided, said that the Association desired to let Mr. Asquith and others know that Irish nurses desired registration, and would strive for it until they succeeded.

On the motion of Miss Kelly, seconded by Miss

Reeves, it was resolved:-

That Irish matrons and nurses desire to record their united conviction that State Registration has become an urgent necessity for the nurses of the United Kingdom, in their own interest, and in that of the public."

On the motion of Miss Wills, seconded by Miss

Sutton, it was resolved:

"That copies of the first resolution be forwarded,

with a report of this meeting, to the Right Hon, the Prime Minister, and the Chief Secretary for Ireland."

Mr. William Field, M.P., who was present, spoke in support of the resolutions, and at the close of the meeting a vote of thanks was proposed to him by Mrs. Treacy. In doing so she referred to the union which prevailed on this subject between all Irish matrons and nurses. The Prime Minister had said that the opposition to registration in England consisted of 49 matrons of London hospitals, 109 provincial matrons, 100 London doctors, 120 provincial doctors, and 12 chairmen and treasurers of London hospitals. They must bear in mind that against these numbers they had the 20,000 members of the British Medical Association.

The Reported Presence of Prussic Acid in Chlorodyne WE have received a letter from the solicitors of Messrs. J. T. Davenport, Limited, proprietors of Dr. Collis Browne's chlorodyne, referring to a coroner's inquest held on April 27th, at which it was stated that the preparation "contained appreciable traces of prussic acid," and that "a full dose was equal to two drops of hydrocyanic acid." This statement went the round of the newspaper press, and as it was likely to undermine the value of a remedial agent which has btood the test of more than half a century, Messrs. Davenport obtained from a well-known firm of public analysts, Messrs. Helbing and Passmore, who are entirely independent in this matter, a report of the result of their analysis of two bottles of Dr. Collis Browne's Chlorodyne bought by them from different retailers' stocks, which shows that there is no prussic acid, nor any compound of it, in the chlorodyne. As is well known, there is no difficulty in ascertaining the presence of prussic acid in a compound if it is there

Messrs. J. T. Davenport, Limited.

The following is the report of the investigation by Messrs. Helbing and Passmore:-

"As requested, we have purchased at different establishments two bottles of Dr. J. Collis Browne's Chlorodyne, manufactured by J. T. Davenport, Limited, and have made a careful analysis of the same. As a result of our examination we found that neither of the two bottles of chlorodyne contained the slightest trace of prussic acid nor any compound of the same." June 7th, 1909.

The Late Dr. Conolly Norman.

THE Executive Committee recommended to a meeting of the subscribers to the Dr. Conolly Norman Memorial Fund last week that the memorial should take the form of a portrait, to be hung in the College of Physicians, and that a bust and tablet in bronze and marble should be erected in St. Patrick's Cathedral, the portrait to be painted by Miss S. C. Harrison, and the bust to be executed by Mr. Carre. It was resolved that steps should be taken to carry out the proposals as speedily as possible, and to ask the Fellows of the College of Physicians to accept the portrait, and to assign it a place to be hung.

#### Royal College of Surgeons, England.

AT the meeting of the Council of the College, held on Thursday last, the following Examiners were elected on the Board of Examiners in Anatomy and Physiology for the Fellowship for the ensuing collerhysiology for the Fellowing folice relating to the results of the results folice from the results folice for the results folice Carlier.

Carler.

The following were elected on the Conjoint Examining Board:—Elementary Biology—Thomas W. Shore, James P. Hill. Anatomy—William Wright, William H. C. Greene, Arthur Robinson. Physiology—Benjamin Moore, Ernest H. Starling. Midwifery—William R. Pollock, Walter W. H. Tate, Hugh J. M. Playfair, James H. Targett. Public Health (Part I.)—Harold Robert Dacre Spitta; (Part II.)—Richard Deane Sweeting.

#### Royal College of Surgeons of England-The Fellowship.

AT a meeting of the Council, held on Thursday, June 10th, the following members of the College, having passed the required examinations and conformed to the by-laws, were admitted Fellows of the College:

College:—

J. D. Barris, L.R.C.P.Lond., Camb. Univ., and St. Bart.'s Hosp.; W. R. Battye, Captain I.M.S., M.B., B.S.Lond., St. Thomas's and St. Bart.'s Hosp.; T. C. Clare, M.B., B.S.Lond., Birmingham Univ.; A. H. P. Dawnay, L.R.C.P.Lond., St. Thomas's Hosp.; E. A. Dorrell, L.R.C.P., D.P.H.Lond., Bristol, and St. Bart.'s Hosp.; R. Farrant, L.R.C.P.Lond., Westminster Hosp.; A. Fleming, M.B., B.S.Lond., St. Mary's Hosp.; W. H. Forshaw, L.R.C.P.Lond., Sheffield, and London Hosp.; C. H. James, Major I.M.S., L.R.C.P.Lond., St. Thomas's Hosp.; J. L. Joyce, B.A.Cantab., Camb. Univ., and St. Bart.'s Hosp.; F. A. Juler, M.B., B.A.Cantab., Camb. Univ. and St. Mary's Hosp.; C. F. L. Leipoldt, L.R.C.P. Lond., Guy's Hosp.; C. F. L. Leipoldt, L.R.C.P. Lond., Guy's Hosp.; T. W. Letchworth, M.B., B.C.Cantab., Camb. Univ. and St. Bart.'s Hosp.; Aaron Levy, M.D., B.A.McGill, Montreal and St. Bart.'s Hosp.; J. E. R. McDonagh, F.L.S., F.Z.S., L.R.C.P.Lond., St. Bart.'s Hosp.; S. G. MacDonald. M.A., M.B.Cantab., Camb. Univ. and St. Thomas's Hosp.; E. K. Martin, M.B., B.S.Lond., Univ. Coll. Hosp.; W. F. Neil, M.B., B.S. New Zealand, Otago Univ. and London Hosp.; C. Oldfield, M.D., B.S., M.R.C.P.Lond., Leeds Univ.; R. Ollerenshaw, M.D.Vict., Manchester Univ. and London Hosp.; H. R. G. Poate, M.B., C.M.Sydney, Sydney Univ. and London Hosp.; F. C. Pybus, M.B., B.S.Durham, Durham Univ. and St. Bart.'s Hosp.; H. E. Quick, M.B., B.S.Lond., Middlesex Hosp.; P. M. Smith, M.D.Lond., London Hosp.; C. F. Robertson, M.B., B.S.Lond., Middlesex Hosp.; P. M. Smith, M.D.Lond., London Hosp.; R. A. Worthington, M.B., B.A. Cantab., Camb. Univ. and London Hosp.; P. M. Smith, M.D.Lond., London Hosp.; R. A. Worthington, M.B., B.A. Cantab., Camb. Univ. and London Hosp.; P. M. Smith, M.D.Lond., Canb. Univ. and London Hosp.; P. M. Smith, M.D.Lond., London Hosp.; R. A. Worthington, M.B., B.A. Cantab., Camb. Univ. and London Hosp.; P. M. Smith, M.D.Lond., Canb. Univ. and London Hosp.; P. M. Smith, M.D.Lond., Canb. Univ. and London Hosp.; P. M. Smith, M.D.Lond. J. D. Barris, L.R.C.P.Lond., Camb. Univ., and St.

The following candidates, not being members of the

College, were also admitted Fellows:—
V. Z. Cope, M.D., B.A.Lond, St. Mary's Hosp.;
A. C. Devereux, M.B.Edin., Edin. Univ. and Middlesex Hosp.; W. M. Munby, M.B., Ch.B.Edin., Edin. Univ. and Guy's Hosp.

Diplomas of the College Licence in Dental Surgery

were granted to the following candidates:—
V. C. Burt, Charing Cross and Royal Dental Hosps;

A. Cohen, Guy's Hosp. Dental Sch.; R. Highton. Liverpool Univ. (Dental Dept.); G. G. Packe. M.R.C.S., L.R.C.P., St. George's and Royal Dental Hosps.

William John Smith, M.B.Toronto, Toronto Univ. and London Hosp., was admitted a member of the

# Summary of Recent Medical Literature, English and Foreign.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

Tuberculosis in Hospitals for the Insane.—Hutchings (Amer. Journ. of Insanity, April, 1909) discusses the incidence of tuberculosis among patients confined in asylums. The high mortality from this disease in hospitals for the insane has long been recognised, and is still present, though the old belief that such patients are peculiarly susceptible to the disease is no longer held. During the year 1906, 10 per cent. of the deaths of patients in the State of New York were caused by tuberculosis, and during the same year 16.6 per cent. of the deaths in the State hospitals for insane were caused by tuberculosis. It has further been found that the death-rate among women is higher than it is among men. Thus, in the period 1888 to 1906, there were 28,106 deaths from all causes in the New York State Hospitals for the Insane; of these, 15,242 were men, and 12,864 were women. Among the men, 1,463 died from tuberculosis—9.5 per cent.—while among the women there were 2,596, or 20.1 per cent., deaths from tuberculosis. It is not possible to state positively whether the majority of patients who develop the disease are admitted with it or are infected while in hospital, but it is quite certain that the number in the pital, but it is quite certain that the number in the latter class is at all events considerable. As regards preventive measures, Dr. Hutchings recommends careful segregation of infected patients and the use of tuberculin in order to help in making an early diagnosis. This is the great difficulty in treating tubercular insane patients, for in many cases it is not possible to make an early diagnosis of the disease in the insease by ordinary absciolar parameters. the insane by ordinary physical examination. Another very important matter is the avoidance of overcrowding. In spite of the most careful attention to ventilation and cleanliness, overcrowding has been found a most fruitful source of zymotic diseases among the The use of separate pavilions and tents for the treatment of the tubercular insane has been attended with most gratifying results in many hos-

Treatment of Pleural Effusions.—Marsden (Med. Chronicle, May, 1909) reviews the present position of our treatment of pleural effusions. There are in the main two views as to the course we should adopt in such cases. Some writers urge that the fluid should be removed as soon as its presence is recognised, and that paracentesis should be repeated whenever the fluid tends to re-accumulate. In support of this method of treatment it is urged that "no individual can be expected to derive benefit from a pleural effusion," and, further, the early removal gives less risk of cirrhosis and contraction of the lung, bronchiectasis, chronic interstitial pneumonia, and deformities of the chest. The presence of fever need not contra-indicate paracentesis, for a fall in temperature often follows the removal of the toxin-containing effusion. On the other hand, it is urged that a period of from two to three weeks should be allowed to elapse before the fluid is removed. If the fluid is removed during the stage of active inflammation, it re-accumulates rapidly, or active adhesions are likely to take place between the parietal and visceral pleura. Furthermore, it is urged the presence of the fluid is useful in giving rest to the affected lung, and so promoting the process of repair. Dr. Marsden's experience leads him to accept the former teaching, and he believes that the danger of a permanently contracted lung is much greater than is the danger of the formation of adhesions. K.

Excessive Growth of the Beard.—Allworthy (Brit. Journ. of Dermatology, May, 1909) records the case of a man whose beard grew with extraordinary luxuriance. At one period it measured 130 inches in length, in spite of the fact that at times, owing to the hair having become matted and unmanageable, he

had been compelled to cut off considerable portions. The man died when sixty-four years of age, his throat and chest having suffered as the result of the experiment.

K.

Intercostal Rigidity in Lung Disease.—Pottenger (Amer. Journ. of the Med. Sciences, May, 1909) lays stress on the importance of spasm of the intercostal muscles over areas of the lung affected with tuber-culosis as an aid to diagnosis. Pottenger has found this sign constant even in very early cases of the disease, and by its means he believes that he is able to; map out the affected areas of the lung. K.

Prostate Weighing Seventeen Ounces Removed by Suprapubic Route.—Fullerton (Brit. Med. Journ, 22nd May, 1909) reports the case of a patient, æt. 73, who had little urinary trouble until he suffered from retention of urine two days before the operation. There was some hæmaturia, and catheterisation failed to relieve the condition owing to the instrument getting blocked with clot. Suprapubic puncture was resorted to. As the patient had had a severe syncopal attack a few days before owing to weak heart, it was with some misgiving that operation was decided on. The operation was accompanied by the greatest difficulty, on account of the finger being unable to reach the deeper part of the gland. In order to deliver the prostate it was found necessary to split it longitudinally, and remove it in halves. The operation was conducted under ethyl chloride, and lasted fifteen minutes. The patient suffered from very severe shock for some hours after the operation, but subsequently did well. A small mulberry calculus was also removed from the bladder.

Partial Thyroidectomy.—Dunhill (Brit. Med. Journ., 22nd May, 1909) gives his experience of this operation on 113 cases. Two of these were for malignant on 113 cases. Two of these were for malignant goitre, 88 for exophthalmic goitre, with one death early in the series. Twenty-three were performed for the parenchymatous or adenomatous variety without a death. All the cases were done under local anæsthetic. death. All the cases were done under local anæsthetic. Local anæsthesia is very much safer, there is less danger of injuring the recurrent laryngeal nerve; it is not followed by vomiting and retching, which is extremely painful and may lead to secondary hæmorrhage. Local anæsthesia also permits the patient drinking three pints of water within the first two or three hours after constraints. two or three hours after operation, which the author insists on as a prophylactic for any tendency to acute thyroidism. The writer's results have been very satisfactory even in cases in which the symptoms have progressed until organic changes have taken place in heart muscle. The author considers that every should be treated medically for about three the heart muscle. months if there is continuous improvement, which shows definite signs of going on to complete cure. Operation should be performed as soon as it is recognised that the patient is not improving, and before she has lost so much ground that she will require much nursing back to health after the cause of the disease is removed. The nutber werell the cause of the disease is removed. The author usually removes one lobe and half the isthmus at one sitting, and if that is not sufficient, half the second lobe a few months later. He is strongly averse to the crushing of the gland before its division. This procedure is not necessary to control hamorrhage, and the toxic secretions from the bruised glandular tissue are absorbed by the veins and lymphatics, giving rise to acute thyroidism. The author inserts a glass drainage tube for two days down the raw surface of the cut lobe through a separate incision, and says that the amount of blood-stained secretion that is got rid of into the dressings is sometimes amazing. This thryotoxin would be otherwise absorbed with perhaps fatal results.

## **NOTICES TO** CORRESPONDENTS, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a Distinctive Signature or Initial, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home cr abroad. Fereign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs 15.12. Messrs. Dawson and Sons are our special agents for Canada.

CONTRIBUTORS are kindly requested to send their communica-tions, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

JOHNSON ON GOUT.

A CORRESPONDENT has sent us the following, culled from the original "Life of Johnson":—Dr. Samuel Johnson, being attacked by gout at the age of 66, wrote to Boswell on July 6th, with this couplet:

What dignity attends the solemn gout;

What conscious greatness if the heart be stout.

MISTERCORDIA.—Apply to the Medical Officer of Health for the

Miserscordia.—Apply to the medical officer of account district.

Dr. S. M.—The work you speak of is conceived in the true scientific spirit of patience and humility. If true, it must one day secure recognition at the hands of the profession, although, unfortunately, the recognition is so tardy as to be of little avail to the earnest worker. That your theory expresses part of the truth appears to us fairly certain, that it may lead to the discovery of the whole truth appears probable. Meanwhile, right or wrong, it forms a valuable contribution to contemporary methods.

THREE PHASES OF A PHYSICIAN.

CORDUS, the Physician, who was in the habit of taking his fees at the termination of his patient's disease, described the practitioner in three different characters in a facetious epigram, which has been thus translated:—

Three faces wears the doctor: when first sought, An angel's—and a god's the cure half wrought; But when that cure complete, he seeks his fee, The devil looks less terrible than he.

The sentiment contained in this jeu d'esprit recalls the old couplet:— THREE PHASES OF A PHYSICIAN

The sentiment contained in this jeu d'esprit recalls the old couplet:

"The Devil was ill, the Devil a saint would be;

The Devil was well, the devil a saint was he;

M.D.Glasse. (South London).—If in doubt, you had better try Calmette's test—a drop of tuberculin solution (glycerin. free) is placed on the conjunctiva, and if the patient be tuberculous, this proceeding is followed by a conjunctivitis within six to fourteen or sixteen hours. A positive reaction is of the greatest value, but a negative result does not exclude the infection, and in that event the test should be repeated two or three times.

W. T. G.—The occasion was a special one, and the space limited. Perforce, therefore, the invitations had necessarily to be limited.

GENERAL PRACTITIONER.—An apology having been made, and the circumstances fully explained, we cannot see that our correspondent would gain anything by pursuing the case further.

# Meetings of the Societies, Tectures, &c.

WEDLESDAT, JUNE 16TH.

ROTAL MICROSCOPICAL SOCIETY (20 Hanover Square, W.).—
8 p.m.: Dr. J. A. Braxton Hicks: Exhibition of the Better-known Tropical Parasites.
MEDICAL GRADUATES COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. P. J. Freyer Clinique (Surgical).
5.15 p.m.: Lecture: Mr. C. Dent: Persistent Symptoms after Head Injuries.

Head Injuries.

NORTH-EAST LONDON FOST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—Clinics: 2.30 p.m.: Medical Out-patient (Dr. T. B. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks).

ROTAL SOCIETY OF MEDICINE (DERMATOLOGICAL SECTION) (20 Hanover Square, W.).—5 p.m.: Dr. Wilfred Fox and Dr. Rolleston: A Case of Leuksemic Infiltration of the Skin. And other Cases.

ROYAL COLLEGE OF PHYSICIANS OF LONDON (Pall Mall East).—
5 p.m.: Dr. W. S. Lazarus-Barlow: Radioactivity and Carcinoma (an Experimental Inquiry). (Croonian Lectures.)

Whiting); Surgical (Mr. H. W. Carson); X.-Rays. 5 p.m.: Medical In-patient (Dr. G. P. Chappel). 4.30 p.m.: Lecture-Demonstration: Mr. A. de Prenderville: On the Administration of Ansethetics.

ministration of Anesthetics.

PRIDAT, JUNE 18TH.

ROYAL SOCIETY OF MEDICINE (SECTION FOR THE STUDY OF DISEASE IN CRILDREN) (20 Hanover Square, W.).—Provincial Meetings at Edinburgh. N.B.—Fellows of the Society are entitled to attend and to speak at all Meetings.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies-Street, W.C.).—4 p.m.: Mr. M. S. Mayou: Clinique (Eye).

NORTH-East London Post Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—10 a.m.: Cllinic: Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Operations: (Mr. W. Edmunds). Clinics: Medical Out-patient (Dr. A. G. Auld); Eye (Mr. R. P. Brooks). 3 p.m.: Medical In-patient (Dr. R. M. Leslie).

Central London Throat and Ear Hospital (Gray's Indread, W.C.).—5.45 p.m.: Lecture: Dr. Abererombie: Pharynx and Naso-Pharynx.

## Appointments.

HEATH, A. D., M.D.Lond., M.R.C.S., M.R.C.P.Lond., Physician-in-Charge of the Skin Department of the General Hospital, Birmingham.

MASSON, CHARLES ARMIT, M.B., Ch.B.Aberd., Senior Assistant Physician at Inverness District Asylum.

MCKILLOP, A. C., M.B., Ch.B.Edin., Junior Assistant Physician at Inverness District Asylum.

MOORE, IRWIN, M.B., C.M., Assistant Surgeon to the London Throat Hospital.

NIALL, W. G., M.D., M.S.R.U.I., Medical Officer to the Guildford No. 2 District.

#### Bacancies.

Northern Infirmary.—House Surgeon. Salary, £100 per annum, with board, etc. Applications to Mr. Duncan Shaw, W.S.,

Northern Infirmary.—House Surgeon. Salary, £100 per annum. with board, etc. Applications to Mr. Duncan Shaw, W.S., Inverness.

Birmingham General Dispensary.—Resident Surgeons. Salary, £170 per annum, with furnished rooms, fire, lights, and attendance. Applications to Ernest W. Forrest, Secretary.

Royal Surrey County Hospital, Guildford.—House Surgeon. Salary, £100 per annum, with board, residence, and laundry. Applications to the Hon. Secretary at the Hospital.

Brecon and Radnor Asylum, Talgarth, Breconshire.—Assistant Medical Officer. Salary, £170 per annum, with board, furnished apartments, attendance, and laundry. Applications to the Medical Superintendent.

Royal South Hants and Southampton Hospital.—House Physician. Salary, £100 per annum, with rooms, board, and washing. Applications to T. A. Fisher-Hall, Secretary.

Weston super-Mare Hospital.—House Surgeon. Salary, £100 per annum, with board and residence in the Hospital. Applications to the Hon. Secretary.

Sheffield Union Hospital.—Assistant Medical Officer. Salary, £100 per annum, with apartments and rations. Applications to Albert Edwd. Booker, Clerk to the Guardians, Union Offices, Sheffield.

East London Hospital for Children and Dispensary for Women. Shadwell, E.—Resident Medical Officer. Salary, £100 per annum, with board, residence, and laundry. Applications to W. M. Wilcox, Secretary.

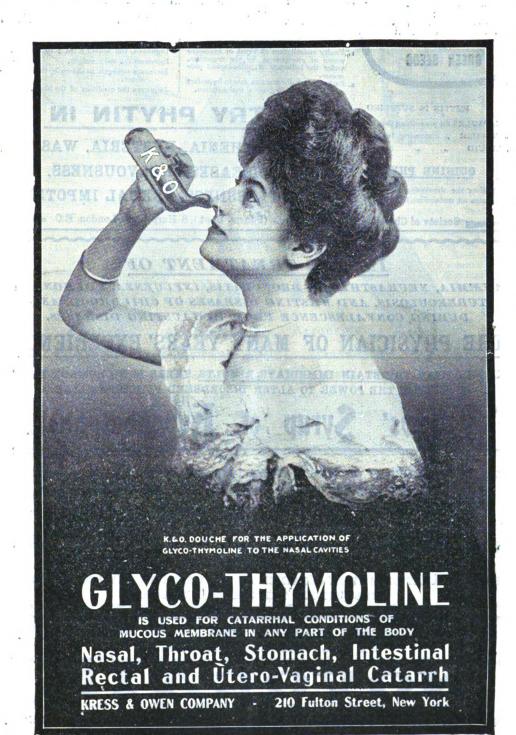

West Riding Asylum, Menston, near Leeds.—Fourth Assistant Medical Officer. Salary, £106 per annum, with board and apartments. Applications to the Medical Superintendent. London County Asylum, Colney Hatch, New Southgate, N—Junior Assistant Medical Officer. Salary, £160 a year, with board, furnished apartments, and washing. Applications to H. F. Keene. Clerk of the Asylums Committee, Asylums Committee, Asylums Committee, Officer, Salary, £100 per annum, with board apartments and partments applications to Headen Place, London, S.W.

### Births.

CRAIG.—On June 7th, 1909, at 18 Merrion Square, Dublin, the wife of James Craig, M.D., F.R.C.P.I., of twin sons Fox.—On June 10th, at Beccles, Suffolk, the wife of George E. Fox, F.R.C.S., J.P., of a daughter.
Jewesbury.—On June 10th, at Stoughton, Guildford, the wife of R. C. Jewesbury, M.B.Oxon., M.R.C.P.Lond., of a son Montgomery.—On June 10th, at "Fermain." Maidenhead, the wife (nee de Steig?r) of Edwin Cecil Montgomery, M.R.C.S Eng., L.R.C.P.Lond., of a daughter.

### Beaths.

DIAMOND.—On June 8th, Victoria Gonville, wife of W. H. Diamond, M.D., and daughter of the late Sir Gonville Bromhead, Bart., of Thurlby, Lincolnshite, aged 66 years.

Sole Agents for Great Britain, THOS. CHRISTY & CO., 4-10 & 12 Old Swan Lane, Lendon, E. C.

Examined and approved by the INSTITUTE OF HYGIENE, 31 Devonshire St., Harley St., W., where their preparation can be seen, and its properties and value can be explained.

# PHYTIN

PHOSPHORUS SALT

**OREEN SEED8** 

Contains 22-8 per cent. Natural Phosphorus. Discloses Rational Phosphorus Therapeutics.

#### INDICATIONS:

- Faulty assimilation of Food or excessive waste of phosphorus by the organism, under the influence of pathological pro-
- g. Pathological phenomena due to imperfect metabolism, or to general malnutrition.

THERAPEUTIC EFFECTS

Improves the appetite (in 3 to 4 days). Increases the body weight. Increases strength, as shown by the dynamo-

Improves the condition of the blood.

#### PHYTIN IS SUPPLIED

In CAPSULES for prescribing (box of 40 ... 3/-)

" POWDER " dispensing (25 gr. ... 4/-)

# TRY PHYTIN IN

. (20 ... ... 1/3) NEURASTHENIA. HYSTERIA. WASTING

# Valentine's Meat-Juice

Where a Powerful, Energetic, Non-Irritating, Rapid Blood-Building Nutrient is required, in a Concentrated Form, Easily Administered and Readily Tolerated by the youngest child, when all other forms of food fail, Valentine's Meat-Juice is recommended by eminent medical authorities and extensively used in Hospitals devoted to the treatment of

# Diseases of Children.

Thos. N. Vincent, M. D., Visiting Physician St. Ann's Infant Asylum, Washington, D. C.: "I have used Valentine's Meat-Juice in St. Ann's Infant Asylum, in the treatment of cases of Diarrhoea, incident to Teething in infants of delicate constitutions, and find it in every way satisfactory. It is easily assimilated, attended with no untoward symptoms and agrees in cases where other foods fail and when milk, prepared in any way used at present, also failed. I can testify also to its usefulness as a nutrient in Scarlet Fever and Measles."

H. H. Powell, M. D., Professor of Obstetrics and Diseases of Children, Western Reserve University, Cleveland, Ohio: "If I were asked in what class of cases Valentine's Meat-Juice has proved of most value in my hands, I should say Cholera Infantum and the Dysenteries of Children. Nutritious and stimulating, it is so agreeable to the taste as not to be refused by any Infant, however sick, and is so entirely assimilated as to leave nothing to irritate the lower bowels."

Dr. Raphael Raimondi, Consulting Physician to the Montmartre Nurseries, Paris, France: "I use Volentine's Meat-Juice with Nurslings eighteen months to two years old. These very weak Babies derive great benefit from the use of this tonic preparation. I give it to Debilitated Infants, after they are eighteen months old, in doses of one teaspoonful in thirty gramms of boiled water twice a day, and to be continued for a month."

Physicians are invited to send for brochures containing clinical reports.

For Sale by European and American Chemists and Druggists.

# Notes and Comments.

SINCE the time of Hunter's famous experiment of the successful graft-The Transplantation ing of the cock's spur into its comb, of Limbs. many interesting essays have been made in a similar direction. Teeth, skin, bones, nerves and blood-vessels have all been transplanted, and success has been reported even with the kidneys of smaller animals. If some results recently published by Dr. Alexis Carroll, of the Rockfeller Institute, of New York, are confirmed, medical science may be said to have added another substantial fact to the foundation of future achievements. Dr. Carroll's first attempt to transfer the leg of one dog to that of another had practically succeeded when the fox-terrier that was the subject of the experiment unfortunately died of pneumonia. A second attempt is said to have had a more favourable result, and the two dogs were said to be "getting on very well with their grafted legs." If this can be done in the case of dogs, there is no particular reason why a similar transplantation should not be practicable in the case of man. Should some millionaire have the misfortune to lose a leg or an arm, it would probably be within the purchasing power of his money to procure a limb for the purpose of grafting from some fellow mortal less richly endowed with worldly pelf. Meanwhile, the operation is hardly within the range of practical surgical politics. Its chief purpose in life at present seems to be to give a delightful opening to the raging propaganda of the anti-vivisectionists.

contemporary, OUR sprightly "John Bull's" John Bull, eager to emulate the feats of its sixpenny prototype in the exposure of scandals—but, apparently, without that proto-Biscuit Manufactory. type's command of machinery for verifying information—is becoming extraordinarily au fait at discovering mares' nests. It is but two or three weeks ago since it was let in over a pièce de résistance for the week, which was placarded over the Kingdom. The editor had no idea that he was not printing a fresh and piquant article, but he really should be on his guard against believing everything that is told him. His ingenuousness and his confidence in the essential accuracy of human nature would do more credit to-let us saya Don Quixote than to a London editor who aims at being smart. More unfortunate even than the aforesaid fiasco is the series of articles on lunacy scandals which he has been endeavouring to work up, for they involve much unnecessary publicity in matters which are best buried in the sanctuary of private life. In a recent issue he discovers that repeated attempts at suicide are evidence of insanity, or, at least, that prodromal symptoms of insanity recognised by medical men may in a short time lead to suicide. If John Bull had that knowledge of the world which is possessed by the man in the street, to say nothing of medical men, he would know that half the patients in asylums are strongly convinced of their own sanity, and equally strongly of the loss of mental stability in their comrades in misfortune. Wherefore let us urge our contemporary to beware of the perils of biscuit manufacturing which it seeks to impress on its fellows. The pleasure of distributing biscuits is no doubt great; the task of preparing them for distribution is beset with pitfalls.

A Musical Medico. The justices of Colwyn Bay are being much exercised in their minds as to whether or not they have been hoaxed about a medical certificate.

A Manchester woman was summoned to appear before them to answer a charge of defrauding a railway company. When the day for hearing arrived, the defendant did not appear, but a certificate arrived by post saying that she was not able to attend on account of "serious illness." The document was signed "W. Miller," and the kindly disposed bench adjourned the case for a week. At this adjourned hearing, however, the defendant again was not present, and a detective was called for the company, who explained that he had been to see the woman, and asked her about "Dr." Miller. To him she pointed out that the said Miller was not a doctor, but "a friend who went to play music to her every night"! The friend's address was asked for, and two or three different ones were given, and finally, said the detective, he was asked to call next day, when the woman hoped she could give it correctly. This evidence seemed to have ruffled the bench, for the chairman breathed dark threats about issuing a warrant if the defendant did not appear at the next sitting. We do not think the bench really have much ground for complaint, even if the facts are as stated, for the "W. Miller" in question made no pretence to being a medical man, and if a certificate is lightly accepted without inquiry as to the identity of the giver, there is no reason why the latter should not be a friend who "plays music every night," if he likes to take the responsibility of certifying.

Medical
"Freedom."
WE are always somewhat amused at the doings of the "People's League of Medical Freedom," and we have never been able to understand what class of medical "freedom" the people of this country do not enjoy. Every man is free to go to the doctor he likes, the

quack or herbalist he affects, to buy the medicine he likes, with the exception of a few scheduled poisons, which under the new Pharmacy Act he can now get in any quantity he desires at a horticultural dealer's if a pharmacist refuses to serve him. A recent meeting of the League at Southport, however, has given us a hint of what that body really desires. They object to the practice of coroners holding inquests on people who die without benefit of registered medical practitioners, and we can quite understand why the "People" find this custom inconvenient. It is awkward for the adherents of herbalists and similar freebooting practitioners when an inquest is held on a person who has died during an illness attributed to "worms" or "sluggishness of the blood," and the post-mortem reveals an appendicular abscess or such condition curable by ordinary surgical methods. At the meeting in question the following resolution was adopted:—"That this meeting expresses its gratification at the demand for medical freedom which is now being made by unorthodox schools of medical practice, as evidenced (1) by the efforts of the medical herbalists to obtain a charter; (2) by the recent determination of the homœopaths to establish a college for the training of their students; and (3) by the increasing activity of the Nature Cure Association, the Emmanuel Society, and other like organisations." We cannot help wondering if the homoeopaths will be flattered by finding themselves dans cette galère.

Anæsthetics for Animals.

INTERESTING stories are told by the Daily News of anæsthetics given of late years to animals for surgical and other purposes, stories which, in some instances, put a certain strain on the

credulity, but which we feel we can accept without reserve on the authority of our contemporary. We are told of a chimpanzee and a "particularly ferocious" lynx which were anæsthetised for surgical operations at the Zoo, and a rhinoceros (in New York) which needed a pound and three-quarters of chloroform and half a pound of ether before sinking into oblivion. Also of a lion, at Earl's Court Exhibition, which lost an eye and was supplied with an artificial substitute. The lion, accustomed to the realities of life, promptly scratched out this aid to comeliness when he came round from the anæsthetic, we are informed. Of this story we may say that we have no difficulty in believing the second part if we are prepared to swallow the first. The greatest trial, however, is when we are informed that fish in the Prince of Monaco's Oceanographic Institute were chloroformed in order that photographs might be taken of them, especially as the incident is narrated without the horror and aversion of our contemporary. Is it not rather inconsistent of a rabid anti-vivisection organ to pass lightly over experiments made on fish for purposes of photography and to rave furiously against an experimenter who inoculates a guinea-pig that he may save a child?

Mr. Chapman and Treatment.

THE "Normyl" treatment of alcoholism has been so little to the fore of late that we had begun to think the "Normyl" it had taken its place with the other innumerable cures which have preceded it into oblivion.

However, a report has just been published in the press by the Rev. Hugh Chapman, the honorary secretary of the "Normyl" Association. The report gives little or nothing in detail as to the results of the treatment, but consists for the most part of a repetition of the old claims made on its

behalf. It is significant, however, that the encomiums are pitched in rather a lower key, and there are one or two remarks which seem to possess an interesting significance. Mr. Chapman disclaims the secret cure of the drunkard, but says: "I am profoundly impressed by the value of religion in this connection, my own experience being that the vast majority of those tempted to drink have a certain disposition towards devotion. . . . must be a desire to be cured, and the immense help of hope, a re-awakening of love which is the death-blow of selfishness, and a willingness to observe the conditions. . . . Abstinence from alcohol during the treatment (twenty-four days) and regular recourse to the medicine are the sole con-Normyl will do the rest." Of this we can only say that, given a man addicted to drink who is filled with a desire to be cured, who is of devotional temperament and seeks the aid of his religion, who is determined to eschew selfishness. who is strong in hope of being cured, and who will begin by keeping from alcohol for nearly a month, given all these conditions, and Normyl or any other drug has precicus little to do. Long before any drugs were used for alcoholism men have turned from strong drink by the aid of repentance, religion and a desire for a new life. The Salvation Army can supply examples ad lib.

### LEADING ARTICLES.

THE LUST FOR BLOOD AND THE INSANE HOMICIDE.

THE recent occurrence in Liverpool of a series of murderous attacks upon women has once again brought into prominence the existence of a curious form of criminal homicide, of which it is difficult to fathom the motive. In the present instance the assaults have all been committed within a restricted area, and have extended over six weeks. During that period a large number of women, some of them having been decoyed into alleys and stabbed with a sharp instrument, while others have been similarly attacked in the street. Fortunately none of the victims have been mortally wounded, although in some instances abdominal wounds of a most serious nature have been inflicted. most recent attack a young woman was accosted in the street by a man who had the appearance of a foreigner, but, suddenly, noting the glint of steel in his hand, she gave an alarm, which resulted ultimately in the aprehension of a man, who may or may not be the author of a series of crimes. Under the circumstances it is, of course, out of the question to comment upon the case, but as a considerable amount of attention has been drawn to these sensational occurrences, it may be desirable to put forward a few remarks upon the general aspects of homicidal attacks of this particular kind. The instance that at once occurs to the mind is that of the series of murders of unfortunate women that took place in London in the years 1888 and 1889. In all there were eleven victims, who were rapidly disembowelled and the viscera removed in a manner that suggested the murderer was possessed of anatomical knowledge, and that earned for him the popular sobriquet of "Jack the Ripper." The author of this extraordinary series of crimes was never brought to light, but the fixed popular belief is that he died later in a criminal lunatic asylum. A somewhat similar set of murders has recently

baffled the police of Berlin. The lack of a prominent motive and the facts attendant upon these crimes at once suggest they are the outcome of insanity. They are, in short, the work of human tigers, in whom there is a predominating lust for blood, which can be satisfied only by the sacrifice of certain victims in a given manner. The subject was recently touched upon by Dr. Claye Shaw, in an address delivered before the Medico-Legal Society on "A Prominent Motive in Murder." The main subject dealt with is the lust for blood, to which he has given the name "hæmothymia." He points out that when the intellectual side of his mind leads a man to commit a crime, delusional insanity is fairly easily held to mitigate his responsibility. On the other hand, as regards a similar influence from the emotional side, however strong and compelling in its force, however morbid in intensity, the plea of "affective" or "emotional" insanity is rarely, if ever, put forward, except save, possibly, as an extenuating circumstance. Yet feeling and emotion are the wellsprings of action in life. The ultimate origin of the fight for life, for food, for progress, for social safety, is to be found essentially in the tapping of the emotional or affective promptings. Indeed, says Dr. Shaw, "will itself is so largely made up of emotional element that it is doubtful if it could exist without it; certainly, any preponderance or diminution in the intensity of the emotional part of the content of any state of willing must seriously affect its validity." The blood lust appears to fall well within the emotional field. The sight or smell of blood affect most living creatures of the higher types in a curious way. It is obvious that in savage states the sight, smell, and sometimes the taste, of blood must be closely connected with the preservation of life by the procuring of animal food and by the destruction of foes, and that these associations must play an important part in the evolutionary stages of the mammalian brain and in its most highly-finished product in the genus homo. It is possible that the French Revolution was prolonged by the continual flow of blood from the guillotine. In hand-to-hand fighting, again, the fury and the desire to kill are more intense than under modern methods at long ranges. The problem, from a pathological point of view, is, what state of mind can that be which, without external provocation, prompts to an apparently uncontrollable desire for blood, as in the Jack the Ripper cases? Dr. Shaw's view is that there is probably an emotional complex present, not merely the desire for blood, but also an admixture with the love of notoriety, of a wish to frighten the public, and of self-satisfaction at finding the prominence attained, the last acting as an incentive to repetition of the process to feed the flame of vanity." A further influence appears to be that the lust for blood grows in intensity, possibly also from indulgence, until it becomes ideomotor. After all said and done, we feel that modern psychology has yet much to discover in the analysis of the mental processes that can produce so monstrous a type as that of the multiple murderer of the "Jack the Ripper" type. From a more practical point of view, it may be urged upon the experts in insanity that possibly prevention may, in this

direction, prove better than attempts at cure. For instance, it would be well to devote some of the vast capital and energy now expended in the care of the insane towards the prevention of the marriage of the unfit. This may be done both by educating the nation as to the undesirability of persons of insane stock, and of the absolute necessity of putting an end to the short-sighted and, to our minds, absolutely indefensible practice of discharging so-called "cured" inmates from lunatic asylums, and allowing them to breed freely and thereby multiply lunacy upon the face of the earth. Were this practice stopped a great step would have been taken in advance with regard to the diminution of criminal lunacy of all kinds and degree.

### CURRENT TOPICS.

### Post-Mortem Examinations in Workhouses.

THERE are in some quarters sentimental objectors to the making of post-mortem examinations, just as there are objectors to dissection, to vaccination, to experimental research, to orthodox drug treatment, and, indeed, to all and every branch of scientific medical research and practice. At this time of day, however, it comes somewhat as a shock to find certain guardians of a first-rate provincial city banning the holding of post-mortems in workhouse hospitals with bell, book and candle. Yet that is what occurred recently at Manchester in connection with the Withington Workhouse Hospital. Mrs. Garrett, one of the guardians, objected to the holding of post-mortems on the ground that, no reports being made, they were of advantage to no one except the medical man who performed them. She added that she was opposed altogether to the granting of this "liberty" to young doctors who came to their institution, making the hospital a practising-ground for the completion of their education. These remarks, we gather from the Manchester Evening Chronicle, were supported by a "Dr. Garrett," who held that post-mortems in these institutions should be placed on the same footing as in the case of the wealthy, where they took place only and solely when there were suspicions of foul play. With regard to the latter contention, it may be remarked generally that the post-mortem examination is absolutely indispensable for the progress of medical knowledge, and that it is not infrequently permitted by educated persons on purely scientific grounds. As to the remarks of the lady guardian, we can only say that if fully-educated and experienced medical officers are required, their services must be paid for at corresponding rates. Moreover, it is absolutely necessary that every medical man must go through his educational experience somewhere or other, and the least that the community may expect in return for their support of voluntary and of State medical institutions is that they be reasonably, discreetly and humanely used as training centres for medical men. Sentiment of the flabby kind that would forbid post-mortems is akin to that of the anti-vivisectionist who declaims against a scientific experiment on a lower animal, but who does not hesitate to eat a lobster that has been boiled alive, or to allow his wife to wear egret feathers

torn from a nesting bird, or haply to play a salmon for an hour or two before that noble fish is brought to gaff.

# Poor-law Medical Officers and the Budget.

In many quarters an outcry has been raised against the increased expenses imposed on individuals by the recent Budget. Of these complaints some are sound, some questionable, and others unwarranted by the facts of the case. Amongst the "hard cases," however, is undoubtedly that of the Poor-law medical officers who have to provide their own drugs. As a rule, they are badly paid, while in some instances the allowances are scandalously low. In any event, the Poor-law medical officers are obliged to consider ways and means most carefully, and their financial balance is likely to be seriously disturbed, if not annihilated, by the extra cost of drugs, due to the increase of spirit duties. However, there is a ray of hope in most valleys of despair, and it may here be found in the direction of cheaper preparations. With a little ingenuity and a fair acquaintance with the resources of the Pharmacopœia, it is possible in a vast number of cases to substitute (we use the word in its original sense) watery solutions, extracts, preparations of active principles, and so on, in place of the spirituous preparations. Any capable pharmacist could effect a great saving in this way without any damage to therapeutic efficiency. The lesson of economy in drugs is one that ought to be inculcated with advantage in our voluntary as well as our Poor-law medical institutions.

### Strawberry Culture in England.

THE importance of fruit culture in the United Kingdom is perhaps hardy realised as a national asset, although of late years it has undoubtedly undergone great and encouraging developments. Under present conditions a great deal of money goes out of the country for produce that could be just as readily and cheaply grown at home. The dearness of land and the cost of railway carriage are not remotely concerned with this untoward result. Meanwhile, one of our best fruit crops is the strawberry, for which the soil and climate of the British islands is peculiarly favourable. It is of value, not only as a fresh fruit, but for the production of a staple foodstuff in the shape of jam. In our desire to maintain the reputation of this wholesome and delicious fruit in our issue of June 9th we condemned a practice that has grown up in certain quarters of placing rotten manure under the ripe berries to keep them off the soil. The practice is clearly prejudicial to the health of consumers, and we suggested that it should claim the attention of medical officers of health in strawberry-growing districts. We have since received a letter from a gentleman, who writes on behalf of the Hampshire growers, and indignantly repudiates the practice so far as that county is concerned. We gladly receive the assurance that clean straw is used by the Hampshire fruit gardeners, but that fact does not disturb our trustworthy information that in certain other parts of England rotten means is freely used. The matter

seems to be worthy of a question in Parliament, and of the attention of the Local Government Board, if to that body, as we imagine, pertains the duty of controlling the sanitary conditions under which is produced a foodstuff consumed to so enormous an extent as the strawberry.

## Education and Medical Advice.

In England, during the past few years, much has been done to bring the educational system of the country into relation with medical opinion. The regular inspection of school-children, with the constant visits to the school thereby entailed, renders it almost impossible for any radical fault of school management or arrangement to escapenotice. In Ireland, on the other hand, medical menhave no connection with the primary or secondary school system, and no detail of school work comesunder their notice or control. As is natural, such a condition has led to very serious results. As we have often pointed out, the school buildings are notoriously unsuitable from a sanitary point of view. The arrangement of school work, as regards hours, examination system, and so on, has been framed without any regard to the health of the children. The National and Intermediate Boards of Education are without any expert advice in sanitary or medical affairs. We are glad to see that the Irish Medical Association has had its attention drawn to the matter. At the Sligo meeting a couple of weeks ago, on the motion of Mr. J. B. Story, of Dublin, a resolution was passed demanding the appointment of a medical man on each of the educational boards of the country. Ifhowever, this resolution is to have any force, it must be pressed on the authorities by agitation in Parliament and elsewhere. It is a pity that the Irish Medical Association missed a chance of demanding the appointment of medical men as inspectors under the Intermediate Board a few months ago, when, for the first time, that Board introduced a system of inspection.

# The Annual Meeting of the British Medical Association in Beltast.

It is over twenty years since the British Medical Association held a meeting in Ireland, and consequently considerable interest is being taken in the meeting to be held next month in Belfast. programme of business is gradually approaching completion, and in many of the sections subjects of special interest are down for discussion. Thus in the Section of Medicine the main discussion will be on angina pectoris, to be introduced by Sir Clifferd Allbutt. In the Section of Obstetrics Dr. Hastings Tweedy, Master of the Rotunda, will open a discussion on the fruitful, if unsatisfactory, subject of endometritis. A new feature is a section of Hæmatology and Vaccine Therapy, of which, as is natural, Sir Almroth Wright is President. He will give an opening address dealing generally with the subject of vaccine therapy. A less necessary section is that of Pharmacology and Therapeutics; the subjects to be dealt with here might easily have been disposed to other sections, and the multiplication of sections is unwise. As in previous years, a pathological museum is to be a feature of

PERSONAL.

the meeting, and collections of specimens dealing with tuberculosis, diseases of warm climates, cancer of the uterus, and X-rays, are being specially made. When we add that arrangements are in hand for pleasant engagements of a social nature, it will be seen that any members of the profession who can visit Belfast next month may be sure of enjoying the meeting.

### PERSONAL.

Dr. Lazarus-Barlow delivered, on the 17th inst., the second of the Croonian lectures on "Radio-activity and Cancer."

AT a Garden Party on July 8th, at 3.15 p.m., the medals and prizes at Guy's Hospital will be distributed to the students by His Grace the Duke of Devonshire.

The President of the Board of Education has appointed Mr. Ralph H. Crowley, M.D., M.R.C.P., to be an assistant medical officer of the Board. Dr. Crowley, who was for some time honorary physician of the Bradford Royal Infirmary, at present occupies the post of medical superintendent of the Bradford Local Education Authority.

The League of Mercy announces that the Comptroller of H.R.H. the Prince of Wales's Household has issued invitations in the name of T.R.H. the Prince and Princess of Wales, Grand President and Lady Grand President of the League of Mercy, to a reception at Marlborough House on July 7th.

THE Medical School of St. Thomas's Hospital will hold its annual prize-giving on Friday, June 25th, at 3 p.m. The prizes will be distributed to the students by the Rt. Hon. Alfred Lyttelton, K.C., M.P., in the Governors' Hall.

THE Annual General Meeting of the Research Defence Society will be held at the house of the Royal Society of Medicine, 20 Hanover Square, W., on Friday, June 25th, at 5 o'clock. The Earl of Cromer, President of the Society, will take the chair. Other speakers will be Sir James Dewar, Sir Arthur Conan Doyle, the Hon. Walter Guinness, and Professor Starling.

Dr. W. Wynn Westcott, J.P., Coroner for North-East London, was yesterday elected President of the Coroners' Society of England and Wales, and Mr. Walter Schröder, Deputy Coroner for Central London, was re-appointed honorary secretary of the Society.

A COMPLIMENTARY dinner was given at the Grand Hotel, Charing Cross, on the 17th inst., to Dr. J. F. W. Tatham, who is retiring from the office of Superintendent of Statistics at the General Register Office.

The annual Welsh medical dinner was held in London, on June 15th. Dr. D. C. Lloyd Owen, F.R.C.S., was chairman, and amongst those present were Sir John Tweedy, Mr. Henry Morris, P.R.C.S., Mr. Ellis Griffith, M.P., Messrs. Lynn Thomas, C.B. and Howell Evans (hon. secretary of the committee)

THE Finsbury Borough Council have appointed as Medical Officer of Health Dr. A. E. Thomas, of Chester, in succession to Dr. Porter, who has been appointed Medical Officer of Health to the Borough of Marylebone.

THE Prince of Wales, on the occasion of his visit to Midsomer Norton, Somerset, on June 23rd, will present the badge of hon associate of the Order of St. John of Jerusalem in England, of which he is Grand Prior, to Dr. Worger, of Radstock, and the society's vellum certificate to Mr. Lloyd Harvey, of Radstock, for services rendered by them for ten years to the cause of first aid to the injured.

DR. OTT, of Marienbad, who attends King Edward during his visits to the Bohemian Spa, has been summoned to London to examine and report upon the King's condition. It is believed that it will depend upon Dr. Ott's opinion whether King Edward will go to Marienbad this summer or to some other spa.

AT a meeting of the Royal Humane Society in London a testimonial was awarded to Dr. Harry Brown, the Medical Officer of the Lunatic Asylum, Pretoria, for his attempt to rescue a man who was drowned while bathing in a disused quarry there on February 3rd. After diving three times into the quarry, the bottom of which is covered with barbed wire, Dr. Brown got the man out, but too late to save his life.

Dr. John Hall, of London, a medical graduate of Glasgow University in 1859, has left the balance of his estate, estimated at about £35,000, to the Senate of the University of Glasgow as an endowment for the foundation of tutorial fellowships in connection with the study of surgery, medicine, and midwifery at that University, to be called "Hall Tutorial Fellowships." The election is to be made by a body consisting of the professors of surgery, medicine, and midwifery; and the fellowships are to be awarded after examination. Each of the fellowships is to be of the value of £200 per annum, and to be paid in advance at the beginning of each session, and there are to be as many of these fellowships as the income will admit.

DR. EDWARD BLAND, of Sandiacre, Derby, who died on April 9th, left estate of the gross value of £12,390, with net personalty £9.125. He bequeathed £500 each to the Midland Institution for the Blind, Dr. Barnardo's Homes, the National Lifeboat Institution, and the Nottingham General Hospital; £200 to the Nottingham Children's Hospital; and £100 each to the Nottingham General Dispensary, the Nottingham County Cricket Club, the vicar of Sandiacre for charitable purposes. The residue of his estate is left for the erection of four almshouses in Sandiacre, to be known as the "Bland Almshouses."

This year the meeting of the British Association will be held at Winnipeg, Manitoba, under the presidency of Professor Sir J. J. Thomson. The inaugural meeting will take place on August 25th, when Professor Thomson will assume the presidency in succession to Mr. Francis Darwin, and will deliver an address. The following day the sectional meetings will commence, and the sittings will extend to September 1st.

Professor E. Rutherford will preside over the Mathematical and Physical Science section. The other presidents of sections are: Chemistry, Professor H. E. Armstrong; Geology, Mr. A. Smith-Woodward; Zoology, Mr. A. E. Shipley; Anthropology, Professor J. L. Myers; Physiology, Professor E. H. Starling.

TWENTY-FOUR cases of cholera and one death from the disease were notified in St. Petersburg on June 17th. Altogether there are 111 patients suffering from cholera in hospital.

HIS MAJESTY'S ship *Philomel*, which has been for some months on the Somali coast, has been ordered to Colombo in consequence of a serious outbreak of scurvy among her crew. The Sirdar will in consequence proceed to Egypt by mail steamer.

# A CLINICAL LECTURE

ON THE

## TREATMENT AND DIET IN INFANTILE GASTRO-ENTERITIS.

By PROFESSOR LEON DELMAS, M.D., .
Of the Faculty of Medicine of Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

GASTRO-INTESTINAL disturbances are especially frequent in the young during the hot season, owing to the peculiar vulnerability of the digestive tract during the first two years of life, more particularly during the first few months of life. Dentition used to be regarded as the most important factor in the production of infantile enteritis, but it is now relegated to a secondary position.

Infantile diarrhœa is met with in infants brought up at the breast in whom it occurs almost invariably in the form of fugitive indigestion or slight catarrhal enteritis. In some instances infants brought up at the breast by wet nurses, who are in the best of health, nevertheless suffer from diarrhœa. This may be explained by the fact that the diarrhœa is mainly due to the influence of the external temperature even more than the food, for the simple reason that the external temperature modifies the intestinal flora and provokes intestinal catarrh; this diarrhœa is, as a rule, a mild affection.

The same remarks apply to infants fed on sterilised milk, provided that the milk is sterilised on the spot. In course of transit non-sterilised milk will have fermented, and the injurious substances resulting from this fermentation resist late sterilisation. It is, however, especially in the bottle that the changes take place, and bottles with long rubber tubes are particularly dangerous.

Statistics show that the mortality during the first year of life constitutes something like one-quarter of the total mortality, and that about one-half, sometimes more than one-half, of the infants dying during the first year succumb to affections of the digestive tract.

Infantile diarrhœa presents different clinical types which it is important for practitioners to be familiar with from the point of view of both prognosis and treatment, but we cannot deal with these on the present occasion. Suffice it to say that simple acute grastro-enteritis sometimes comes on suddenly in the midst of health, with vomiting, fever and colic. As a rule it is preceded for some days or weeks by dyspeptic disturbances such as sickness, flatulence, alternations of constipation and diarrhœa, etc. Once it has supervened, the attack of enteritis may assume either a grave or a mild form.

The mild form is almost always primary; it is ushered in by more or less marked febrile symptoms, such as a flushed face, a rapid pulse, a hot skin, thirst and loss of appetite. The abdominal symptoms, however, attract most attention. The child is in pain, as shown by its restlessness, its incessant crying, and the drawing up of the legs on the abdomen, pressure over the belly is painful and makes the child scream. The stools are frequent, liquid and copious. Yellow to begin with, though mixed with mucus and undigested casein, and occasionally streaked with blood, they soon become green. The tongue is covered

with a yellowish fur, and there may be nausea or sickness. The breath has an odour recalling that of chloroform or russet apples.

Acute grastro-enteritis is almost always accompanied by sleeplessness and restlessness, and the little sufferer becomes captious and irritable. These symptoms may last for ten days or a fortnight when, under suitable treatment and hygiene, the fever subsides, the appetite returns, the diarrhœa diminishes and little by little things return to normal, though the infant remains weak and ailing for some days because, be the attack ever so mild, it always causes great loss of weight.

The grave forms of gastro-enteritis are only met with during the summer heats, and attack principally debile, ill-nourished infants. It commences much in the same way as the mild form, but very soon displays points of difference. The temperature may run up to 104° F., the urine becomes scanty, the stools more frequent (15 or 20 in the 24 hours), they soon become brownish and extremely offensive, sometimes greenish and acid, sometimes colourless and exhaling a musty odour. In the last case the attack often assumes the form of infantile cholera. The motions are acrid and irritating, so that in spite of every care the buttocks and lower limbs become covered with erythema, the skin is excoriated, and we get superficial ulceration over the heels, ankles and buttocks. The infant may be reduced to a state of extraordinary weakness within a few days, the muscles become flabby, the eyes appear much larger than usual, and are surrounded by dark circles. Finally, convulsions and pseudo-meningitic symptoms supervene.

What then is the proper course to pursue when a child presents diarrhea? The medicinal treatment varies according to circumstances. Laxatives are indicated at the onset when the diarrhea is accompanied by fœtid flatulence and undigested food. Small repeated doses of castor oil may be given for four or five days, and this may be associated with equal parts of syrup of gum. The daily dose of castor oil need not exceed min. xv. under six months of age, and min. xl. under twelve months. After six months it may advantageously be given in the following form:—

Syrup of manna Syrup of gum Castor oil

Small doses of calomel (gr. 2 or 3) have been recommended, but this drug is not desirable under six months of age.

Opiates are indicated after the first few days if the stools are very frequent and liquid, and if the evacuations are accompanied by a good deal of pain. Needless to remark that when we give opium we must closely watch its effects, so that it is best administered in small, divided doses at frequent intervals. The daily dose should not exceed min. xii. of laudanum.

Subnitrate of bismuth may be given in doses of from gr. 15 to 30 daily to combat copious, refractory diarrhœa. Lactic acid has been recommended in green diarrhoa of very young infants, and yields good results.

Lastly, intestinal irrigation has been advised in acute enteritis, injecting some three-quarters of a pint or more of boiled water containing per cent. of chloride of sodium. These injections are of great service, repeated once or twice a day, when the enteritis mainly affects the large intestine. They allay the colic and fætid evacuations and they are quite unobjectionable and easy

Whatever medicinal treatment be adopted the most important thing after all in dealing with infantile gastro-enteritis is the prophylactic treat-

In presence of an attack of acute gastro-enteritis the first indication is to place the child on water diet. This means suppressing food of every kind for from twenty-four to thirty-six hours, giving only boiled water. After the water diet we have to feed up the little patient, and here the difficulties begin. Milk, however prepared, boiled, raw, sterilised, pure, diluted, and what not, may not be tolerated. Some success has attended the use of buttermilk or kephir. Sometimes these agree, sometimes not, it is a question of time, environment and individual idiosyncrasy. The best thing, perhaps, is to go back to the vegetable infusions so much in favour with our forefathers, so after the period of water diet the infant should be given a decoction of rice or pearl barley. Barley water is made as follows:-

Put a tablespoonful of pearl barley in a pint of water, boil for twenty minutes, and pass through a hair sieve. Then add sufficient boiled water to make a pint. Keep in a bottle that has been scalded and close with a cork that has been boiled. Decoction of oats is made in the same way

Decoction of cereals may be prepared as follows: take a tablespoonful of wheat, rye, oats, barley, maize and bran. Lightly heat in the oven or on an iron plate, then grind in a coffee mill or rub down to a pulp in a mortar. Stir up with a quart of water, boil and evaporate to about half its bulk (it must boil for at least two hours). Pass through a hair sieve and add water enough to make up a quart. To be kept in a bottle that has been scalded.

Dr. Comby's vegetable decoction is also extensively employed :-Wheat, pearl barley, crushed maize, dry white haricot beans, dried peas, lentils; an ounce (or one tablespoonful) of each. To be boiled for three hours in three quarts of water, to be passed through a sieve, add a little salt (dr. 5 of kitchen salt). There remains about a quart of liquid, which is sufficient for the day's use, and it may be thickened, when given, with a teaspoonful of rice, flour, barley meal, oats or wheat for every four ounces of the decoction.
All such decoctions must be freshly prepared,

in fact, it is best to prepare them day by day. They readily undergo fermentation, so that it is undesirable to keep them more than twenty-

Tisanes " of vegetables are also much employed. The formula recommended by Dr. Remy is the following:-

Carrots, oz. iss. Potato, oz. ii. Turnips, oz. ss.

Dry haricot beans jāā dr. iss. Dried peas Water, one quart.

These are boiled for four hours in a covered saucepan and then passed through a sieve. Add enough boiled water to make up the quart, together with 70 grains of salt. With this bouillon porridges can be made of rice, flour, potato meal or toasted bread.

The child can be fed on these vegetable decoctions for two or three days, but infants who cannot digest milk require something more substantial, and this is why the porridges are recommended.

Dried beer yeast has yielded excellent results in the treatment of infantile gastro-enteritis. yeast can be given in doses of about half a drachm in the twenty-four hours (Ed. or in the form of levurine extractive) mixed with sweetened water. In this form it is always well received by children, who are at the same time placed on water diet or other appropriate regimen. Under its influence the sickness promptly subsides, the stools become less fœtid and the constitutional symptoms abate.

It is when we begin to feed the child again that most care is required, for too sudden resumption of a milk diet is apt to be followed by relapse. For very young infants nothing equals human milk, failing this we may give milk diluted with boiled water or buttermilk, or we may try kephir made with skimmed milk or with ass's milk. Fortunately it is not often necessary to have recourse to these preparations, the child tolerating diluted milk after a stage of vegetable infusions.

After an attack of gastro-enteritis it is impossible to lay down precise rules for the resumption of We are fain to feel our way. In some cases we can give a tablespoonful every two hours or every hour, in others a teaspoonful every halfhour. All we can do is to try what the little patient can tolerate. In another twenty-four or thirty-six hours we may venture to go a step farther, and increase the quantities. It is unquestionably better to alternate the administration of milk with doses of rice water or vegetable infusion, which may also be mixed with the milk. For infants between two and four months of age we may give an ounce of milk with the same quantity of rice water, or vegetable infusion. quantities may also be doubled for infants between four and eight months, and may reach five to eight ounces for children between eight and fourteen months.

There are two excellent preparations which may be made use of, one alternately with milk, the other to mix with it, or to be given in lieu thereof for a time, viz., milk flour and malted flour.

The milk flour, provided it be fresh, is an excellent adjuvant. Half-a-teaspoonful is mix d with from two to four ounces of water, yielding a solution liquid enough to pass through the feeding bottle.

The malted flour is a cheap food, but requires some care in its preparation. Rice flour is made into a clear pap, two teaspoonsful of flour in a pint of water, for example, boil it gently, taking care to stir it all the time (a quarter of an hour). It is then sweetened and allowed to cool to 160°F. Some barley water is then added, which is prepared as follows:-Grind some malt in a coffee mill and put a teaspoonful of the flour in a tumbler of warm water (not exceeding 130° F.,

so as not to destroy the diastase). It is allowed to stand for a quarter of an hour. A tumbler of this water is mixed with the pint of sweetened rice pap, which soon becomes semi-liquid. This action is allowed to continue for twenty minutes, when it is filtered and used in the feeding bottle. This preparation is well liked by young infants, the dose to be according to age.

It is hardly necessary to remark that this mode of feeding must not be adopted to the exclusion of the others, but the malted pap is certainly the product which can be given for the longest time to the exclusion of milk (from four to eight

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by J. Jackson Clarke, F.R.C.S., Surgeon Royal National Orthopædic and Hampstead and N.W. London Hospitals. Subject: "The Clinical Examination of Spinal Cases."

#### ORIGINAL PAPERS.

#### PASSIVE HYPERÆMIA IN THE TREATMENT OF DISEASE.

By R. ATKINSON STONEY, F.R.C.S.I., Visiting Surgeon to the Royal City of Dublin Hospital.

In the summer of 1906 I spent about three weeks in Bonn, attending the hospitals where Prof. Bier was working. While there I had the opportunity of seeing large numbers of cases which were undergoing treatment daily by various forms of hyperæmia, and other cases which had been cured by this method of treatment. I was so impressed by the results which were being gained there that, before leaving, I obtained some of the appliances used and brought them back to Dublin. Since then they have been extensively used at the Royal City of Dublin Hospital, and it is the general impressions which I have gained from their use during the last two and a-half years that I wish to bring forward, without going into the very vexed question as to the exact manner in which hyperæmia brings about its curative results.

There are two main forms of hyperæmia, active and passive. Active hyperæmia is caused by the applica-tion of heat. This form of hyperæmia I do not intend to discuss, but shall confine my remarks to the second, or passive form of hyperæmia. There are two principal methods of producing this kind of hyperæmia—by the elastic bandage and by cupping or suction glasses. It was for the treatment of tubercular disease that this passive hyperæmia was first introduced more than 16 years ago by Bier, but of recent years its use has been extended to the cure of other forms of inflammation, both acute and chronic, and, curious to say, it would appear that good results follow more certainly and quickly the use of this treatment, not in the tubercular cases for which it was first suggested, but in the cases of inflammation due to other causes.

Bier himself explains that he got the idea of applying passive hyperæmia for tuberculosis from the following observations made by the older physicians. Farre and Travers, in 1815, and Louis, in 1826, called attention to the frequent appearance of pulmonary stenosis in phthisis, explaining it by the pronounced anæmia of the lungs which this form of heart disease produces. The observations of those physicians have been confirmed without exception, so that Frerichs (1853) could pronounce the dictum: "Pul-Frerichs (1853) could pronounce the dictum: "Pulmonary tuberculosis, be the relation of this disease to tuberculosis what it may, is the usual end in diseases of the pulmonary artery." Conversely, Rokitansky (1838) maintained that diseases of the heart, accompanied by fulness of blood in the lungs, offered immunity against tuberculosis. In his own words:

"A relation of hypertrophy of the heart to tuberculous disease is shown by the result of numerous observations. Out of 143 cases (simple, eccentric, as well as concentric hypertrophy), I find in 15 cases there is now extinct tuberculosis of the lungs. In all other cases-persons of variable age, sex, occupations, etc. -there never was a tubercle, from which it can be concluded that both diseased conditions cannot exist at the same time in one and the same individual, and especially that in the presence of the named disease the heart no tuberculosis, especially pulmonary berculosis, can develop." The same immunity tuberculosis, can develop." against, tuberculosis Rokitansky ascribed to people with distortions of the spine, in whom, as is well with distortions of the spine, in whom, as is well known, pronounced stases develop in the circulation of the lungs. Rokitansky's observations have been repeatedly confirmed, but they also have been frequently attacked. And though the large majority of physicians who have expressed themselves on this subject do not allow his assertions to stand in the comprehensive way that he expressed them, nevertheless they acknowledge the correctness of the principle. less they acknowledge the correctness of the principle and admit a relative immunity of congestion of the lungs against tuberculosis. I shall say very little concerning the treatment of tuberculous cases by passive congestion, as my experience has been neither very extensive nor promising.

First, as regards the method of producing passive hyperamia, or venous congestion by means of the elastic bandage. This is the method that is most usually adopted for tuberculous cases, specially tuber-culous disease of joints; it is also used, however, for extensive inflammations of a septic nature, as for instance, osteo-myelitis in both the acute and chronic stage, cellulitis, inflammation of tendons and their sheaths, as onychia, acute and chronic arthritis, etc. The first general rule to be observed is that in tuberculous cases the bandage is applied for 1 to 2 hours daily, whereas in all other cases it is applied for two periods of 8 to 11 hours, or one period of 16 to 22 hours out of the 24. The bandage can be used to produce a passive hyperæmia of the extremities or of the head and neck; in the latter case a band of ordinary black elastic encircling the neck below the larynx is used. By a special modification in the technique, a passive hyperæmia of the shoulder-joint can be produced, but as yet there has been no satisfactory means found of producing this hyperæmia in the hip-joint. Considerable care must be exercised in the application of the bandage or grave injury may result. And it is probably to a large extent owing to improper application that unfavourable results have been so frequently reported as following this method of treat-ment. The bandage is to be applied with sufficient force to offer some resistance to the venous flow, but none to the arterial. The pulse therefore distal to the bandage should not be reduced in volume, and the limb should not become colder, but rather warmer than its fellow, and should be of a bright or dark red colour, not purplish. But one of the best criteria of whether the bandage is properly applied or not is the sensation of the patient. Passive congestion, by whatever method it is produced, should never cause pain; on the contrary, one of its most striking features and greatest advantages is that it relieves pain if present. The further from the seat of disease that the bandage is applied the better, as a rule; so that in disease of the hand or wrist the bandage should be placed on the upper arm. Again, the bandage should cover an extensive surface, and the position should be slightly changed from day to day to prevent the skin from becoming chafed; especially is this advisable where the bandage is left on for long periods. Sometimes in the case of very thin patients, or in those with an unusually thin skin, it is very hard to prevent some pain and chafing of the skin under the bandage, but by washing the skin with alcohol, and placing a layer of cotton wool between the bandage and the skin, much may be done to avoid this trouble.

From my personal experience of this method of treatment of tuberculous disease of joints, I cannot say that I have seen any good results, but I must at once confess that this is probably my fault, and not the fault of the method, as I have not had the most suit-

able cases in which to try it, and have never had the patience to continue the treatment for the necessary length of time. According to Bier, about nine months is the least time in which this method can be expected to produce a marked result or cure. I must say also that while in Bonn I saw several cases in which this method of treatment had brought about excellent results. Extensive cases of tuberculous arthritis with nun erous sinuses, which had healed and left a movable joint. Bier himself confesses that he has had the least satisfactory results in the case of the knee-joint, and that in the majority of cases operative treatment is better here, as even if a cure is obtained by passive congestion the joint is usually stiff and liable to become contracted, and therefore no better than if the treatment had been shortened by early operation. In the cases of tubercular disease of joints also, it is In the cases of tupercular disease of joints also, it is much more difficult to produce the right degree of congestion than in other affections, and there is a much greater danger of doing harm. If the hyperæmia employed is excessive, either in degree or duration, cold abscesses are liable to form and spread with amazing rapidity. But in other pathological condi-tions I have obtained most gratifying results. For instance, in the treatment of onychia the following two cases may be taken as typical examples of what may be expected.

CASE 1.—A girl, et. 13, was seen in the dispensary on Wednesday, April 28th, 1909, the middle finger of the right hand had been sore for three or four days, and so painful that the patient had scarcely slept at all for two nights, the whole finger was greatly swollen, suppuration was evident on the front of the terminal phalanx. An incision one centimetre long was made and a small quantity of pus was evacuated, a congestion bandage was put on the upper arm and a loose dressing applied to the finger. The bandage was removed after 10 hours, there was no pain, the patient slept all night; for the next four days the bandage was applied for 22 hours daily, there was no further discharge, the pain, stiffness and swelling all rapidly disappeared, and the finger was well within a week.

Case 2.—A girl, æt. 22, was seen in the dispensary, CASE 2.—A girl, æt. 22, was seen in the dispensary, with great pain, swelling, redness and tenderness at side of nail of left little finger; this condition had been present for some days, and the patient had not slept the night before owing to the pain. There were no distinct signs of pus present. The bandage was applied to the upper arm for 22 hours on three consecutive days, pain and applied to the upper arm for 22 hours on three consecutives. secutive days, pain and swelling rapidly disappeared, and the finger had returned to its normal condition when seen on the fourth day. Instances like these might be multiplied indefinitely. As examples of might be multiplied indefinitely. As examples of cases of bone infection treated by this method, the following two cases may be quoted:-

CASE 3.—A young man, æt. 22, was admitted to the hospital in February, 1907; there was considerable swelling of the lower part of the left thigh, a sinus was present on the inner side, where an abscess had been opened in the country a month previously. On probing, an extensive surface of bare bone on the back and inner surface of the lower end of the femur was felt. An X-ray photograph showed widespread disease of the bone. An operation was performed and the bone freely exposed, and an opening made into its interior. There was no sequestrum, but a very large part of the lower end of the femur, including the whole of the popliteal surface was bare and rough. Both the elastic bandage and a suction glass were used in the after-treatment, and the parts healed up and the patient left the hospital apparently cured at the end of eight weeks. In May, 1908, the patient returned with a small sinus discharging thin purulent material in the track of the old scar, there was some swelling also of the lower part of the thigh. The bardage was again applied, and the sinus rapidly healed and the patient was discharged cured in three weeks. Since then he has remained well, and has been able to do all his ordinary work as a farmer.

CASE 4.—A man, æt. 32, was admitted to hospital on March 20th, 1909; he was sent up from the country for amputation of his foot. Six months previously he developed an abscess on the back of the leg just above the heel, this was opened, but the inflammation spread. When admitted the whole region of the ankle was

enormously swollen, numerous sinuses were present on the back, front and inner side of the ankle, bare bone could be felt on probing these various sinuses, and a probe could be passed apparently through the lower end of the tibia from one opening to another. There was also complete ankylosis of the ankle-joint, as shown by an X-ray photograph; this also showed great enlargement of the lower end of the tibia, with great enlargement of the lower end of the tola, with a cavity in the interior. The parts were thoroughly opened up and the cavity in the bone scraped; no definite sequestrum was found. The bandage has been used almost daily since a few days after the operation. The pain, which before and for the first few days after operation was excessive and prevented the patient from sleeping, disappeared immediately on the application of the bandage, and the swelling has almost entirely subsided, the sinuses are nearly all closed, and the patient will soon be able to leave hospital and return to his work.

It is, however, in cases of gonorrhœal arthritis, perhaps, that the most striking results are seen, the pain and stiffness disappearing with really marvellous rapidity. I have not had an opportunity of treating any of these cases in this way, but I had the opportunity of seeing some while at Bonn. One case specially impressed me, a man with acute gonorrhœal arthritis of his wrist. He assured me that the pain, which had been extreme, disappeared entirely within half an hour after the application of the bandage, and he was able to move the wrist to a slight extent without pain, while the bandage was in position.

Let us now pass to the consideration of the second great method of producing passive hyperæmia—that is, by means of cupping or suction-glasses. These are made in all shapes and sizes, from very large ones, which will cover a secreting mammary gland, to a very small one, which will just cover a boil. A partial vacuum is produced in the smaller ones by a rubber ball attached to them, and in the larger ones by means of an exhausting pump. This method is applicable to all cases of localised inflammation whether acute or chronic, specially to those where there is an opening in the tissues. The general method of use is to apply the cup daily for 45 minutes. During the scance the treatment is arranged approximately thus: the glass is allowed to remain in position for five minutes, and is then removed for three minutes; this sequence of events is repeated from six to eight times. Here again the same care must be taken that an excessive hyperæmia is not produced. The part within the glass should not become a dark purple, but a bright red, and no pain should be caused. If there is pain the glass is improperly applied. Of course, strict asepsis should be observed, the glass being boiled before use, and the surrounding tissues cleaned. It is well also to smear the skin in the neighbourhood of a sinus with some antiseptic ointment (personally I use one composed of equal parts of tinct. benz. co. and vaseline), to prevent irritation of the skin by the discharges and to assist the glass in adhering to the part. A glass of a sufficiently large size to include a fairly broad area of tissue around the opening should always be chosen, as otherwise a strangulation of the parts may be produced, or the edges of the opening may be pressed together and the discharges prevented from, rather than assisted in, escaping. In some cases, especially where there is a long sinus leading to an extensive cavity, it may be advisable to place a drainage tube in the opening before applying the cup. In the cases of tubercular sinuses and abscesses, the degree of vacuum produced may be somewhat greater, and the duration of application may, with advantage, be somewhat longer than in cases of acute septic in-flammation. With the assistance of this method of treatment, it will be found that boils, carbuncles, abscesses, tubercular sinuses, etc., will heal with greatly increased rapidity. The following case is fairly typical of what may be expected.

CASE 5.—A boy, æt. 16, was admitted to hospital in March, 1909, with a large acute abscess on the back of his neck. A small incision was made, and about 1½ oz. of pus evacuated. A cup was applied on three successive days. The discharge rapidly decreased, and the patient was sent out cured on the fifth day.

In abscesses of the breast it is, perhaps, that the most gratifying results are seen, for by means of a very small incision, followed by the application of a cup, even severe cases may be cured in a short time without extensive scarring, deformity, or loss of function. My personal experience of the treatment of this class of disease has been limited to a few cases. Bier says that he has seen excellent recoveries where he has had to open as many as eight to ten abscesses successively by separate small incision. In puerperal mastitis it is generally advisable to use a large cup which will include the whole breast, and many of these cases will recover under this treatment without advancing to the stage of suppuration. In other cases, where a definite abscess has formed, especially if it is superficially placed, it is often better to apply a smaller cup to the involved portion of the breast.

It must always be distinctly understood that this method of treatment by passive congestion is not intended to replace or do away with the general principles of surgery, or that by its use operative measures can be abandoned. The rule of surgery still holds good: when pus is present it must be evacuated at the earliest opportunity. But with its help a smaller incision may be used, and tedious after-treatment and drainage may be greatly reduced or done away with.

This method of treatment of abscesses with suction is by no means a new or recent invention, as Nicolaus Florentinus speaks of the treatment of buboes in the following terms:—"Extractio puris cum incisione et suctione—i.e., cum ventosis et cum eis, qui trahunt pus post sectionem et apertionem." Also in some parts of Southern Russia women afflicted with mastitis, at the very beginning of the disease, place over the glands large pots, in which some kerosene has been ignited, and they are apparently convinced of the effectiveness of these large cupping appliances. Bier himself employed cupping glasses and suction apparatus for the purpose of producing hyperæmia for acute inflammation, many years ago, when he was in Kiel and Greifswald, but only for the treatment of furuncle. His intention was not only to produce hyperæmia, but also to suck out with the rarefied air the pus and necrotic shreds, and in this he succeeded. Tilman especially, at his instigation, made extensive experiments in this direction at the Greifswald Polyclinic, but he was not altogether satisfied with the results. He found the appliances too painful for the patients, and the hyperæmia produced altogether too energetic, and herein lies the cause of failure of these early attempts. Of late, however, Klapp, Bier's chief assistant at Bonn, has resumed the treatment in the Bonn Polyclinic, and has extended it to all possible forms of inflammation and suppuration, and has so fully developed the technique that he can show most excellent results.

Space does not permit me to write further of the numerous classes of cases to which treatment by passive hyperæmia is applicable; as the neck bandage for various affections of the head, otitis media, mastoiditis, boils, carbuncles, diffuse acne, etc.; or the use of glasses for tubercular glands, both before and after softening and suppuration; or the treatment of empyema by suction glasses, from which I have had some good results. The various pathological conditions in which passive hyperæmia is being used are continuously on the increase, but in many of them further experience is necessary before it can be definitely stated how much is to be expected from this method of treatment, and here there is a large field open to anyone who is sufficiently interested to undertake investigations on his own account. But it may be asked, cannot congestion hyperæmia do harm? specially in cases of acute inflammation, which in itself frequently leads to grave circulatory disturb-Personally, I have only seen harm done in one case, where a cup was applied over a large carbuncle on the top of an infant's head; after the first day the application of the cup was entrusted to the nurse, and on seeing the case a few days afterwards, I found that an area of skin corresponding to the size of the cup used was gangrenous; this was due not to the treatment itself, but to the way in which the treatment

was carried out, as the cup had been put on with somuch pressure that the tissues were compressed between the rim of the cup and the skull. cases where the glasses are placed over superficial bones or dense, firm membranes, special care must be taken to prevent this strangulation of the superficial tissues. This accident occurred during the first six months after the introduction of this treatment, and since then I have seen no other bad result. In the first edition of his book Bier says: "I am convinced that the greatest mischief can be produced with the remedy in progressed cases of phlegmon of the soft parts. The circulatory disturbance in such cases is so pronounced that gangrene of the attached parts is threatening. And in these cases the removal of the congestion is indicated, and not an increase of the latter? He has however modified his views. the latter." He has, however, modified his views, and in the last edition of his work says: "I admit that there is such a variety of inflammation, but it is extremely rare, and it is not the circulatory disturbance, but the producer of inflammation (essentially bacterial toxins) which kills the tissues. advisable, especially for such physicians as are little experienced in the method, to abstain from the application of congestion hyperæmia in inflammation considerable congestion. At any rate, in such inflammation, whatever abscesses may be present, should be thoroughly incised. To this, however, must be added that in all cases of acute progressed suppuration which I have treated with congestion hyperæmia I have not seen a single case where the agent produced real or lasting harm, and but one in which it was not tolerated on the extremities. Correctly applied, congestion hyperæmia does not mean disturbance, but improvement of nutrition."

# CASE OF BANTI'S DISEASE, WITH PULMONARY PHTHISIS AND HERPES — DEATH FROM HÆMORRHAGE.

BY ALEXANDER DON, M.B., C.M., F.R.C.S., M.A.,

Hon. Surgeon to, and Lecturer on Clinical Surgery, in the Royal Infirmary, Dundee.

THE following case is of interest, partly on account of the rarity of the disease itself, and partly on account of its course and complications. P. came under my care in the beginning of August, 1902, suffering from severe metrorrhagia. She was 46 years of age, married, and the mother of a family of four sons and one daughter, the eldest being 21, and the youngest, the daughter, 7 years. All are healthy, but there were some mishaps between the boys and the girl. No history of syphilis could be obtained either in herself or in herhusband. The lungs and kidneys were healthy, and there was a slight systolic blowing over the apex of the heart. This I thought might have apex of the heart. This I thought might have been due to the secondary anæmia. The pulse-rate was not greatly increased, nor was there any rise of temperature.

The hæmorrhage persisted for about six weeks, with brief periods of cessation, in spite of absolute rest in bed, with elevation of pelvis, and large doses of ergot, opium, and other hæmostatics and sedatives. The blood came in large clots, for which examination per vaginam revealed no evident cause. It was noted at this time that the spleen was enlarged and hard, the notch being quite palpable, and that the tumour reached the pubisand crossed the middle line, but, in view of the severe bleeding and the critical condition of the patient, no minute external examination was made. There were no enlarged lymphatic glands anywhere. No ascites were noted. The colour and consistency

of the blood-clots were at first normal. The patient latterly became extremely pale, with a slightly yellow tinge which I attributed to the loss of blood. She recovered from this illness sufficiently to be able to be up and attend to her household duties.

About the end of September I spoke to her about the possibility of removing the tumour. At that time the microscopic examination of the blood showed no relative increase of leucocytes, nor other marked alteration beyond that explicable by the secondary anæmia, and as the tumour was causing her no immediate inconvenience, she preferred to leave it alone. I explained to her that I might be unable to remove it later, as another hæmorrhage might leave her much weaker than she then was.

In January, 1903, she suffered from a left pleurisy, and was confined to bed for a period of four weeks. Then followed several severe attacks of epistaxis, but no other serious illness. I had been seeing several other members of the family for trivial ailments, and consequently Mrs. P. was under almost continuous observation from her first illness in August, 1902, until her death in September, 1903. She was always complaining of feeling weak, and she seemed to be working beyond her strength. In the beginning of May, 1903, when I called one day as usual to see her husband who was then ill, I found Mrs. P. suffering from severe abdominal pain. I had spoken to her on a recent visit about having the spleen removed, and she had so far consented that I had arranged a consultation later in the day with a colleague to discuss splenectomy. She was attending to her ordinary duties, and I sent her to bed and carefully examined the abdomen. Over the lower end of the enlarged spleen, and extending down to the pelvis, was a long flat tumour 8 inches by 5 inches, and fluctuating. There was no discoloration of the skin. 1

My diagnosed a rupture of the enlarged spleen. colleague agreed with me when he saw her later the same day in consultation, and on aspiration, pure blood was withdrawn. Next day and the whole week following there was a good deal of discoloration of the skin over the tumour, which proved it to be an extensive subcutaneous hæmorrhage. If it had come from the spleen, as I originally supposed, it must have been entirely shut in by adhesions, and superficial discoloration would not have appeared. This swelling gradually became absorbed during the next fortnight and the discoloration also had almost vanished. Some little fluid remained, but was not in large amount and occupied the region previously occupied by the tumour.

About the end of May she developed a slight cough, with temperature running up to 101° and 102° at nights, and this cough persisted to the end, with but little improvement at any time. right apex became dull on percussion, and later a few small cavities were detected. Breathing became very difficult, and by the middle of June she looked moribund. There was a good deal of ascites and dropsy. Diarrhœa ensued with bloody stools, and the ascites decreased. Respiration again improved, and she was soon back to her normal, though feeble, condition. But the skin and conjunctivæ were now distinctly jaundiced and the urine was of a deep brown colour. The urine began to get clearer after three or four days, but she never got out of bed again from June onwards. She had repeatedly slight bilious attacks, a persistent rise of temperature (100° to 103°), and occasional hæmorrhages from the bowel. She occasional hæmorrhages from the bowel. rarely slept, and was very restless at night. On August 11th she complained of severe headache, confined to the right half of the brow and head,

and running back to the line of the ear. The pain was specially severe over the right eye. I gave her 10 grs. of phenacetin, and some menthol ointment to apply locally. Next day she was worse and the pain agonising, and the painful area was all red and swollen like erysipelas. On the third day, August 13th, a herpetic rash appeared, but still the pain was severe, and she required morphia to quieten it. The swelling gradually subsided, and the whole patch became gangrenous. On August 29th hæmorrhage commenced from the lower edge of the slough, and was so severe and persistent that I had to ligature both the anterior frontal branch of the temporal and the supra-orbital arteries. Even then the oozing was pretty bad, but hot water applications, with pressure, finally stopped it. Granulations grew fairly rapidly and the danger of bleeding seemed over, when, on September 10th, she began to vomit. At first blood alone came, and then a brownish fluid mixed with bilious matter. Bleeding recommenced in one of the granulation areas in the forehead. This bleeding and the vomiting continued for most of the day, the vomit in the end being foul and stercoraceous, and she gradually collapsed, became comatose, and died the same evening.

This is the worst eruption of herpes I have ever seen, both as regards the pain complained of and the complete destruction of the affected skin, which extended from the middle line right back to the ear, and from the supra-orbital border to the

hairy scalp.

It may be argued that this is not a true case of Banti's disease, and there is wanting post-morten and microscopic confirmation. blood examination is not so minute nor so accurately detailed as has been the custom in recent blood examinations, but it was sufficient to negative leucocythæmia, and to suggest to me at the time the possibility of bettering the condition of my patient by a splenectomy. The later symptoms—during which there is no record of a blood examination in my notes-viz., repeated hæmorrhages, jaundice, and gastro-intestinal troubles, made it evident to me that I was probably dealing with a case of Banti's disease, as distinct from simple splenomegaly or splenic anæmia. The condition of the patient was, however, then always so poor and uncertain that I did not have sufficient confidence in splenectomy to advocate it to the exclusion of all other treatment. Less than a score of cases of removal of the spleen in Banti's disease, with a mortality of nearly 30 per cent., had been at that time recorded (1), and it was not until I felt how helpless the physician is when face to face with such a case, that I ventured again to suggest splenectomy, and to call in a colleague to strengthen my position. Unfortunately, severe hæmorrhage, with the low condition of the patient, made us hesitate, and no sufficiently satisfactory period occurred later to make me again wish to undertake the risk. It was difficult to erase from one's mind the huge mortality that had followed splenectomy in the past, and it was not until the surgical mortality for the different forms of splenic enlargement had been worked out (2) that one's confidence in the operation was in some measure restored. For leucocythæmic enlargement the mortality in 1903 stood at 96 per cent., for ordinary splenomegaly and splenic anæmia at 37 per cent., and for Banti's disease at 28 per cent. Armstrong (3) in 1906 brings the record up to thirty-two cases with a mortality of 28 per cent., and, where the after-histories could be traced, with almost perfect restoration to health in every case. Johnston (4) in 1908 collected sixty-one cases with a

mortality of 20 per cent. over all, though in the last forty-four cases there were only seven deaths. The immediate mortality, as one would anticipate, was due to hæmorrhage, some of the cases leaving the operating table with tamponage, after ligature had failed. The operation itself, apart from this liability to hæmorrhage, is not deterrent in its magnitude, and, where no adhesions or ascites are present, should show a very small immediate mortality. Ascites, in addition to the usual syndrome, makes operation much more serious, as there would seem at first sight to be little use of removing the spleen and leaving the abdominal cavity to quickly refill with fluid from the liver complications. Tansini has twice, in addition to removing the spleen, done a Talma or Drummond-Morrison operation, where a new circulatory anastomosis is effected by union of liver and omentum to parietal peritoneum, and at least two other surgeons have operated similarly, and while this seems a necessary adjunct to splenectomy in severe ascites, it yet makes one hesitate in frail patients to recommend operation. At no stage in my own case would I have felt justified in suggesting both operations. Nor do I think that the liver would have caused trouble in my case, as the enlargement of the liver was never noticeable, nor was there any ascites except just before the diarrhœa, and it did not recur. That the liver was affected is shown by the jaundice, which was well marked on one occasion, and the yellow tinge, which was never absent during the last eight months, was very suggestive of cirrhosis of the liver. In a number of the cases where splenectomy alone was done, the cirrhosis and ascites have improved pari passu with the improvement in the blood condition, and where the hæmorrhage is a danger it would be madness to attempt hepatopexy-itself a bloody operation—when there is a likelihood of a perfect cure resulting from it.

The terrible anæmia, the constant cough, the cavitation of the apex of the lung, and the difficulty of stopping even the slightest bleeding, were all additional and serious contra-indications in my case. Still I cannot help feeling now that I missed an opportunity for interfering surgically, which would have been at the time I first mentioned splenectomy to my patient. But I then had not sufficient confidence in splenectomy, and I mistook the significance of the metrorrhagia, putting it down as a not unusual occurrence in women nearing the menopause. It was the other hæmorrhages that made me diagnose Banti's disease, and by that time my patient's condition was complicated by the pleurisy and other respiratory lesions. Splenectomy seems rather a too serious operation, and, with probable adhesions, a too difficult one. I could not, moreover, with so slight liver symptoms, give an absolutely hopeless prognosis, even with purely medical treatment, for some of the cases recorded were very chronic (5). Gaucher's case, for instance, lived twenty-five years after enlargement of the spleen was noted. On the other hand, hæmorrhage is so intractable at times that only a few days after discovery of the splenomegaly the patient may die of intestinal hæmorrhage. Such a case is recorded

by Murrell (5).

The ætiology of the disease is still obscure.

The microbic theory, and the There is the inevitable microbic theory, and the hectic temperature certainly suggests a septicæmia condition. In my own case the high temperature seemed to be due to the lung complications, which were so evidently phthisical that I did not trouble to even get the sputum tested bacteriologically. Most writers (6) seem to incline to an intestinal infection as the causa causan. here has been no specific

germ isolated from the alimentary tract, the blood, or the spleen.

What specially determined the herpes is also obscure. She was in bed at the time, and one could hardly suggest the handy "chill." The usuallydescribed inflammatory changes in the central nerve ganglion might have been set up by some septic thrombosis lodging in or near the Gasserian area.

The treatment seems to be in all these cases so far purely surgical, and, once diagnosed, there is no excuse for delay. All the cases medically treated have ended fatally, some of them very speedily, and the mortality of splenectomy will diminish rapidly when these cases are handed over to a surgeon in their earlier stage.

Atherton (3) quotes a case where great benefit followed exposure to X-rays, and he suggests this treatment in all cases prior to splenectomy, and when the patient is too weak for surgical treatment.

#### FLEAS AS TRANSMITTERS OF PLAGUE. (a)

By Professor SHIGA, M.D.

SINCE the discovery of the plague bacillus, suggestions have been made to the effect that certain insects, especially fleas, may serve as the transmitters of the germ. The final demonstration that the rat fleas play a most important part in the epidemiology of plague has been shown by the systematic investigation of the Indian Plague Commission, while Liston has proved conclusively that the common Indian rat flea (pulex cheopis) is the essential agent in the transmission of plague. In Japan, it has been found that the fleas commonly infesting rats do not belong to pulex cheopis, but ct. musculi and cer. anisus. Further, the fleas are most prevalent in hot summer, while plague epidemics usually take place in the cooler season. Thus the non-coincidence of the season of prevalence in plague and fleas, does not favour the flea theory. My present work was planned in view of determining the still uncertain fauna of rat fleas in Japan, and at the same time to see how far they may play their part in the propagation of plague. The observation was made at Yura, where a plague epidemic broke out in 1908. the first step of the investigation concerning the part played by fleas in the epidemiology of plague, they were collected in Tokyo and its vicinity until the month of September, 1908, that is, just before the work was carried out in Yura. During the month of October, when plague thickly infested the town, 2,130 fleas were collected from several sources in Yura, and the result of the examination showed that pulex irritans was found on men, ct. felis on cats, and ct. canis on dogs exclusively, 551 were collected from house rats, which consisted mostly of the common Indian rat fleas. Pulex cheopis, i.e., 255 or 46 per cent., 239 or 90 per cent. were found to be the common Indian rat fleas. As many rats as could be obtained were examined in view of determining how many fleas a rat may harbour, and it was found that a healthy rat carried 2.2 fleas in average, while a plague rat carried 11.3. This wide difference between their numbers agrees with the reports from India and Sydney. In order to see the ratio of the number

<sup>(</sup>a) Read before the Plague Section of the Indian Medical Congress, Bombay, February, 1909.

OPERATING THEATRES.

of fleas in plague, and healthy houses, guinea pigs were let loose in several houses and their fleas were collected. In the experiment, 33 guinea-pigs were set free in 12 healthy houses and only collected 16 fleas, while 36 guinea-pigs were employed in the same number of plague houses, where 249 fleas were collected. The average number of fleas was found to be 20.7 in plague houses, while in healthy houses it was only 1.3. Again, if we average the number to one guinea-pig in each case, the former becomes 9.0 and the latter 0.4.

The Indian Rat Flea. Of the total of 249 fleas from the plague houses, 227 or 90.1 per cent. were identified to be the common Indian rat flea. Therefore, one thinks of the intimate relation existing between the prevalence of plague and this species of fleas. Again, out of the 207 collected from the plague houses by means of guinea-pigs, 49 were proved to carry bacteria, making the percentage of 23.6 and that of the common Indian rat fleas alone is 22.3. This disproportion between the percentage in the Indian rat fleas in both cases may be explained on the ground that the examination of the plague houses and of the 15 human fleas collected from the above observation was made only with the aid of the microscope, which is an imperfect means for deciding a matter of such great consequence. Therefore the culture and animal tests were made with the 43 rat fleas collected from the plague houses with the 15 human fleas collected from the beds of the patients. They proved most clearly the presence of the real virulent pest bacilli in every species of fleas. There is scarcely any doubt as to the possibility of transmission effected by rat fleas, and it is a noteworthy fact that in Japan as well as in India, pulex cheopis plays an important rôle in the plague epidemics. My observation in Japan reaches no further than the confirmation of the infallibility of the result of the elaborated investigation effected by the Indian Plague Commission. Though small in number, the presence of the pulex cheopis provides all the necessary conditions to the spread of plague, and when the germ is introduced into such a place it will produce an epizootic among the rat family. I have been entertaining the view that in Japan plague has been introduced from abroad. It is still more confirmed by the present investigation, which showed that the unwelcome guest, pulex cheopis is continually flowing in at our sea As has been suggested by me, the only means by which we may save mankind from this scourge of plague would seem to consist in routing the evil at its very source, and the international conference on plague will probably afford us all the best possible chance of solving the plague problem.

The Bombay Medical Congress bears an inter-

more frequently. It is announced that a deputation, representing all the London hospitals and the various charitable institutions of the country, will wait upon the Chancellor of the Exchequer to ask for relief from certain proposals of the Finance Bill. It has been pointed out, in a memorandum sent to Mr. Lloyd George, that the hospitals and the other charities are doing a voluntary work of national importance, and that they are, therefore, entitled to relief. At the present time these bodies are exempt from the payment of income-tax upon their invested funds, and it is suggested that whatever the form in which the proposals of the Finance Bill are ultimately passed, a similar exemption should be granted in the case of bequests to charities or land transactions carried out by them.

national character, for it has been planned on a

large scale covering nearly all the leading countries in the Far East, and it is my sincere wish to encourage the holding of this kind of congress

GREAT NORTHERN HOSPITAL. Excision of the Astragalus.-Mr.

EDMUNDS operated on a man, æt. 25, who had been admitted suffering from a tuberculous ankle. The onset of the disease had been insidious, and an abscess had formed and ruptured behind the internal malledus. There was swelling all round the ankle-joint, and at the spot where the abscess had ruptured the skin was infiltrated for about two square inches. The leg was wasted, and the patient's general health had begun to suffer. The question of treatment, Mr. Edmunds said, lay between an amputation and an attempt to remove the disease locally. In children, he thought, amputation is rarely necessary, but in adults the objections to it are largely sentimental. Conservative surgery, however, should always be attempted unless there is grave tuberculous disease elsewhere, for example, in the lungs, in which case tuberculosis of the ankle-joint is probably treated better by amputation. In the present case, although the condition was severe, it was better, he considered, to make an attempt to save the foot than to amputate immediately; nevertheless, at the present time it was by no means certain that this procedure might not become necessary.

An incision was made round the opening of the sinus, which was surrounded by the infected skin, the incision being extended upwards and downwards; a similar incision was made on the other side of the ankle. The joint was then thoroughly exposed and the astragalus with the synovial membrane completely removed (the synovial membrane was that of the anklejoint and of the adjacent joints). The disease had infiltrated the tendons at the back of the internal malleolus, and it was necessary to remove these. The wound was closed, a drain being left in for 24 hours, and the limb put on a rectangular splint. No septic complications ensued, but both incisions became the seat of a slow growing form of tubercle. On a second occasion the patient was anæsthetised and the affected spots in the incisions thoroughly curetted. The ordinary angular splint was found uncomfortable, therefore the foot was enclosed in a pair of splints made of ordinary wire netting; a material which, as Mr. Edmunds pointed out, can be moulded readily and which is light and easily sterilisable.

Mr. Edmunds said that excision of the ankle, in the

strict sense of the word, is a bad operation, because an operation exactly comparable to that performed at the knee-joint would give a poor access to the synovial membrane, and in consequence little chance of removing the disease. Removal of the astragalus, however, afforded quite a thorough access to the joint, and the resulting foot is quite useful; indeed, in little children the loss of the bone can only be detected by careful examination.

The wound was much benefited by the scraping and looks as if it would be healed very shortly. When this is accomplished it is proposed to supply the patient with a peg-leg, so as to enable him to get about without putting his foot to the ground. Six months would have to elapse, Mr. Edmunds said, before putting the foot to the ground.

#### TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION.

MEETING HELD JUNE 10TH, 1909.

The President, Dr. HERBERT SPENCER, in the Chair.

A SHORT communication was read by Mr. J. BLAND-SUTTON on

RED DEGENERATION OF A UTERINE FIBROID associated with the staphylococcus pyogenes aureus. The patient, a primi-gravida, when two months advanced in pregnancy, was seized with an acute and

sudden abdominal pain. At the operation performed 24 hours later the patient was found to have a large subserous fibroid and several interstitial ones. Hysterectomy was performed and the tumours carefully examined by Mr. Somerville Hastings. The larger fibroid amined by Mr. Somervine riastings. The larger motors presented an area of softening, and the surface over this area was covered with lymph. From this "infarcted area" a pure culture of staphylococcus pyogenes aureus was obtained. No micro-organisms were detected in the interstitual fibroids, although they exhibited the red change in streaks.

Mr. G. F. DARWALL-SMITH read a short communication on

#### AN UNUSUAL SOLID TUMOUR OF THE OVARY.

The patient from whom the tumour was removed was a multiparous woman, et. 36. She was found to have a rounded, solid tumour in the right posterior quarter of the pelvis the size of a man's fist. This was removed, and on examination the tissue of the ovary could be seen to be stretched as a capsule over the substance of the tumour proper. The cut surface of the tumour looked like an ovarian fibroma. On microscopical examination, scattered about in the fibrous stroma were seen strands of cells resembling those of glandular epithelium. Some of these cells showed degenerative changes. The diagnosis seemed to lie between endothelioma and adenofibroma.

Dr. W. S. A. GRIFFITH mentioned that he had removed a similar tumour of the right ovary with similar microscopical characters. The tumour showed clinically no signs of malignancy.

A short communication by Dr. KEDARNATH DAS on

FŒTAL CHONDRO-DYSTROPHIA

as a cause of brow presentation and dystocia was read, and notes of two cases of this condition were given.

Dr. J. S. FAIRBAIRN read a paper on

PRIMARY CHORION-EPITHELIOMA OF THE OVARY.

The paper was based on the case of a woman who had had four pregnancies, the last in February, 1905, when the placenta was removed by hand, and the convalescence was protracted. For some months before admission to St. Thomas's Hospital there had been slight, but continuous, uterine hæmorrhage, and for about six weeks abdominal pain, chiefly on the right side. A tender swelling in the abdomen had been noticed by the patient for about three weeks and was the reason for her seeking advice. This was thought on examination to be an ovarian cyst with torsion of the pedicle, but at the operation on January 3rd, 1907, it was found to be a hæmorrhagic tumour of the left ovary with extensive adhesions, but no twisting of the pedicle. It was removed, and also the right ovary, which was cystic and involved in adhesions. The patient showed no signs of recurrence two years after

The tumour was of the size of a small cocoa-nut. It was covered with a white capsule of tunica albuginea, and on section was found to be made up of a mass of hæmorrhagic tissue. Microscopically, the main part of the tumour consisted of blood-clot, fibrin and necrotic tissue, but under the capsule, between the ovarian tissue and the mass of clot were seen the typical syncytial masses with small polyhedral cells of chorion-epitheliomatous growths. No traces of tera-tomatous elements were found. There was no history to indicate anything of the nature of a cystic mole or of chorion-epithelioma elsewhere, and this was taken as sufficient evidence that the growth was solely and primarily one affecting the left ovary.

Other cases of primary chorion-epithelioma in the ovary were discussed. Seven collected by Pick, and others by Michel, Schmaus and Kleinhans were mentioned, but particular attention was directed to two from Doederlein's klinik which occurred in multiparæ, and appeared to be very similar to the one described. Three possible explanations of the origin of chorionepithelioma primary in the ovary offer themselves. (1) It may arise as in Pick's cases and as in chorionepithelioma in the testicle, from teratomatous elements; (2) it may arise from a preceding ovarian pregnancy, and (3) it may be due to transportation of villi from a preceding pregnancy, molar or otherwise. The present case and Doederlein's two were considered as in a class by themselves and as differing from Pick's in that his series included many younger patients (ages 9, 16, 17, 21, 24, 30 and 36), that all except one were nulliparæ, and that there was more definite evidence of a teratomatous origin in the mixed nature of the tumour elements and in the extreme malignancy of the growths. Any further discussion as to the origin of such primary growths must be purely speculative, but as suggesting a possible origin from transported villi, attention was directed to the fact that in two of the three cases specially considered, it was found necessary to remove the placenta manually in the labour immediately preceding the illness.

Dr. Blair Bell read a paper on a case of RUDIMENTARY UTERUS DIDELPHYS.

with ectopia of each uterine body in an inguinal hernia sac, with some remarks on the development of the female genital organs.

The patient was a young woman, set. 20, who had had a double inguinal hernia all her life. Lately there had been attacks of abdominal pain, which caused her to seek advice.

The patient was found to be well-developed and telligent. She had never suffered from monthly intelligent. molimina.

The external genitals were normal in appearance and covered with hair. There was total absence of the vagina, but a circular fringe indicated the formation a hymen. Per rectum no pelvic genital organs could be detected.

At the operation a central sub-umbilical incision was first made in order to investigate the state of affairs. There was a smooth and uninterrupted vesico-rectal Above the true pelvis on either side there was a large hernial orifice. Protruding down the right aperture was the Fallopian tube and ovary; on the left side only the fimbriated extremity of the tube was visible. An incision was next made over the left inguinal canal, and the hernial sac-together with the left uterine body, which was firmly incorporated with it, and the Fallopian tube and ovary—was removed, and a radical cure effected. On the right side the hernial sac and the uterine body were separated from the Fallopian tube and ovary and removed, a radical cure of the hernia being then carried out. The patient made an uninterrupted recovery. On histological examination the left ovary was found to be functional.

The conditions of uterus didelphys and hernia of the uterus were discussed and their relative importance The rarity of actual ectopia of uterine considered. bodies, such as was found in the case described, was mentioned, the only other similar cases on record being those of Roux and Werth. Finally, the "descent" and development of the genital organs was considered in so far as the malformation found in this and other cases seen and mentioned by the author were concerned. The conclusion arrived at was:

That uterus didelphys (and ectopia of the uterine bodies) is due to absence of fusion of the Mullerian ducts, caused by the deficient action of the decussating subperitoneal muscular fibres which normally form the external coat of the uterus; and also (especially when ectopia co-exists) by the deficient formation of uterosacral muscular fibres. As a contributory factor a short genital mesentery plays an important part.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

MEETING HELD FRIDAY, MAY 21ST, 1909.

The President, Dr. E. H. TWEEDY, in the Chair.

THE PRESIDENT exhibited specimens of

FIBROIDS, WITH RED DEGENERATION, removed six weeks after delivery. The woman had been sent to him six months pregnant, and with a large myoma. He kept her over two months in hospital. He induced labour at full term. The child was dead. On the third day her temperature and pulse rose, and on the fourth day the temperature reached 1030. There was great tenderness of the

abdomen, and he became very uneasy about the case. He asked Sir William Smyly to see her in consultation on the fifth day with a view to immediate opera-Sir William advised postponement of the operation, and the woman got gradually better. When her temperature became normal he removed the tumour by supra-vaginal hysterectomy. It showed in a very characteristic manner red degeneration, which was a disease that apparently very rarely occurred save in pregnancy. High temperature was a constant symptom of red degeneration; and this he thought might arise apart from a germ invasion, and be due to absorption of toxic matter found in the degenerating myoma.

Dr. Pureroy said the change noticed in one of these tumours was one of the least common forms of degeneration, and one of which they knew least. He was not quite convinced that the temperature was due to the red degeneration. He was inclined to think that it was connected with a certain degree of localised

sepsis.

Dr. Jellett said he was watching a patient who came to him six months pregnant with a large myoma below the fœtus, filling the pelvis. The patient had been going on very well since. In such a case, where there was a large myoma on the posterior wall of the uterus, filling the hollow of the sacrum, and in which the cervix was jammed above the symphysis, he would like to know how long Dr. Tweedy would allow her to remain in labour. Sometimes tumours that were firmly impacted did get drawn up, but in his case it seemed rather hopeless to expect the tumour to do so.

Dr. ROWLETTE said there were certain points about red degeneration which were fairly fixed. It was commonly found associated with pregnancy, and seldom in other conditions. In almost every myoma associated with pregnancy which he had seen there had been more or less red degeneration. It was certainly a necrotic change of some sort, as the tissue failed to stain. In pregnancy the entire tissue of the uterus was in a highly vascular condition, and something interfering with the blood supply, causing stasis in the veins, might cause a diffusion of blood pigment. There was no doubt that in some cases the red degeneration might give rise to temperature, as it was liable to be affected by septic or putrefactive organisms.

The PRESIDENT, in reply, said the myoma was chiefly situated on the fundus, but also encroached on the lower uterine segment. It was only when he became convinced that the growth had undergone degeneration that he determined not to let her run the risk of another pregnancy. He thought Dr. Jellett's case was plain sailing. His patient should not be allowed even to fall into labour. He should calculate the time of full term, and perform Cæsarian section. After removing the child it would be easy to remove the uterus. The myoma was almost certain to the uterus. The myoma was almost certain to degenerate if she was allowed to fall into labour. He thought there was a toxin that could raise the temperature apart from germ invasion.

Dr. Purefoy read a paper on

SOME PATHOLOGICAL CONDITIONS OF THE URETHRA, which will be published in a future number. In the discussion that followed,

Dr. FitzGibbon recalled a case in which treatment consisted of passing a probe up the urethra, with some cotton wool on the end, and either an antiseptic or some form of caustic applied to the cavity, out of which from 20 minims to half a gram of pus could be squeezed. It gradually healed after three or four months, though he had no doubt that it would have been cured quicker if radical methods could have been

Dr. JELLETT said that he thought that, if possible, in cases of urethral cysts one should try to get away all traces of the cyst wall, and bring the mucous membrane over it, as by so doing there would be a better chance of a permanent result at one operation.

The President said the difficulty of dissecting out an abscess cavity without infecting the raw surface was very great, and he thought Dr. Purefoy's plan

was perfectly surgical. He had seen a condition that Dr. Purefoy spoke of incidentally, but he had not seen it described as an ulceration around the urethra that ran down towards the posterior fourchette. It was absolutely indolent, and occurred in elderly women. It was completely cured by incision, but no other remedy that he know of could cure it.

Dr. Purefox, in reply, said Dr. Jellett's method was theoretically the better one, but it was not always the best in practice. Howard Kelly treated such a case in the radical way, and had to deal with a fistula

afterwards.

Dr. Solomon read a paper founded on a case illustrating the

TOXEMIA OF PREGNANCY COMPLICATED BY RUPTURE OF THE UTERUS.

The President said he did not remember a case that bristled with so many points of interest as this one. How was it that in one case a dead foetus could lie in the uterus and not do any harm, whereas in another case the death of the fœtus was followed by severe toxic symptoms, and how was it that in eclampsia the feetal death was considered of favourable omen? The case was remarkable in that ascites arose as a consequence of the toxin, which he thought showed that the liver had been involved rather than the kidneys. The elucidation of such cases would require the services of a physiological chemist, and showed the deficiency in that respect of our hospitals. Dr. Solomon's case gave positive proof that there was a toxin present within the uterus, although the statement had never been accepted. There was a great future for the hospital that could spend money on a special department to take such cases in hand and investigate them thoroughly. He had thought it required a tight plug in the vagina to cause a rupture of the uterus. This case proved that they could not artificially dilate a cervix; they tore it, but very few were aware that they did so. He had never examined a woman whose os was artificially dilated without finding a cervical tear.

Dr. Ashe thought chloasma might be due to some

form of toxæmia.

Dr. FitzGibbon recalled a case in which rupture of the cervix extending into the lower uterine segment was found about an hour after delivery, though there had been no previous indication of the rupture.

Dr. JELLETT suggested that the cervix was probably in a condition of abnormal softening, in which state it would easily tear. It had been stated that if one found a cervix torn it was proof that the woman had been delivered artificially, but he had seen a patient who had never had a full term child, and never had an operation of any kind, in whom the cervix was

Dr. Pureroy recalled his record of a case in which a lady received a large bilateral tear, as a consequence of the birth of twins that were so small that his ring fitted on to their wrist. He had recorded it as a positive proof that the cervix could tear independently of instrumental delivery. He had never seen a cervix artificially opened without tearing. In Dr. Solomon's case the cervix was not soft. His experience was that it was the hard cervix that tore.

Dr. SOLOMON, in reply, said he had seen a good many cases where patients had said they had never had instruments, and yet the cervix had been torn. He thanked the speakers for their remarks.

A WOMAN named Thompson was on June 17th summoned at the Manchester City Police Court for having failed to notify within twenty-four hours the death of a child she had to nurse. This was the first case in Manchester under a provision of the Children Act. It was explained that the woman was registered by the Chorlton Guardians to nurse one child. The death occurred on May 24th, but was not notified at the coroner's office until over thirty-one hours after the expiration of the period allowed for registration. The summons was dismissed, as the magistrates decided that the woman had acted through ignorance.

# OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

MEETING HELD IN THE ROOMS OF THE MEDICAL SOCIETY OF LONDON, ON THURSDAY, JUNE 10TH, 1909.

Mr. W. H. JESSOP, F.R.C.S., in the Chair.

MR. FREELAND FERGUS showed a case operated upon 'paralytic ptosis" by his method of resection.

Mr. HERBERT FISHER showed an unusual form of cataract, bilateral, in a girl.

Mr. Jessop brought forward a case of "bilateral with complete ophthalmoplegia externa.

Mr. BERGIN showed a case with an unilateral swelling, and Mr. BLAIR one of pemphigus of the conjunctiva; while Mr. HERBERT BELL exhibited a case of unusual elastic adhesion between iris and cornea.

Mr. ARNOLD LAWSON exhibited a case of "congenital glaucoma" treated by Lagrange's iridectomy. The latter was discussed by Dr. Weeks (of Philadelphia), Mr. Brooksbank James, Mr. Treacher Collins, Mr. Odillo Maher, and Mr. F. R. Cross.

Mr. P. H. ADAMS read two papers, the first on A FAMILY WITH CONGENITAL DISPLACEMENT OF LENSES.

The series consisted of a mother and seven out of her nine children who suffered from this condition, but no other instance could be found in the family. In three of the cases the lenses were displaced downwards, instead of the more usual displacement upwards, while in the eldest boy the dislocation was complete, thus leaving the pupil clear of the lens. two members of the family who were unaffected had perfectly normal eyes.

The second paper was on

A FAMILY WITH CONGENITAL OPACITIES OF LENSES.

In this family the great-grandfathers, grandmother, father, and four of his chidren (out of five), as well as the father's sister, showed the peculiar opacities of the lens known as Steller cataract. Posteriorly there were from 3 to 8 primary rays, and numerous secondary ones, while some of them showed Y-shaped markings on the anterior surface as well. The opacities slowly increased throughout life, especially in the front of the lens, while the posterior markings were broader and less defined.

Messrs. A. Hill Griffith and A. W. Ormond read a paper entitled

A CASE OF RETINAL DISEASE WITH MASSIVE EXUDATION AND ARTERIO-VENOUS COMMUNICATION.

The patient was A. J., a female, æt. 31. The left eye had been removed for secondary glaucoma by Dr. Hill Griffith ten years ago. The fundus of the remaining eye showed very tortuous and distended retinal vessels, with varicosity of several of them, and a red blurred optic disc. In the extreme periphery of the fundus, deep to the retinal vessels, was a whitish mass, the limits of which could not be seen. Issuing from the anterior border was a large vein, and running to it an artery somewhat similar in size and colour. The changes in the fundus were probably all due to vas-cular disease. The interest in the case was furthered by the fact that the other eye of the patient was removed for secondary glaucoma simulating an intraocular growth, and, on examination, it proved to be a case of extensive sub-retinal exudation, with retinal detachment and an old organising hæmorrhage, but no growth. The patient's sister also lost an eye from a similar cause, and the same condition was found on pathological examination.

Dr. GEORGE MACKAY reported a very unusual

appearance-

AN EPITHELIAL FILAMENT SIMULATING A THREADWORM in the anterior chamber of the eye of a little girl, æt. 7. The child had always enjoyed good health, had no special illness, had never suffered from worms, and had not complained much about the eye. The filament had been first noticed when she was eight months old. No independent movement had ever been detected in it, but the parents were under the impression that it was slowly increasing in size. The eye was occasionally a little irritable, with a tendency to Iachrymation, and a trace of ciliary injection. The tension was

normal, the media otherwise transparent, and the fundus healthy. The pupil responded to light, though less mobile below than above. At the periphery of the iris, close to the anterior chamber angle, between the 5 and 6 o'clock meridians, a buffy-grey filament about a millimetre in diameter emerged between the fibres of the iris, ascended in close relation to the posterior aspect of the cornea for 3 or 4 millimetres, then bent backwards towards the lower border of the pupil, and, crossing the vertical meridian of the anterior chamber, appeared to rest lightly in contact with the sphincter surface of the iris. Thereafter it bent downwards once more, following the plane of the iris nearly in the 7 o'clock meridian. The structure terminated in a slightly bulbous free extremity, which did not re-enter the iris, nor extend to the angle of the anterior chamber. The arched filament had thus a slight spiral twist from before backwards. The refraction of the eyes was about emmetropic. The vision of the right eye 6/12 fairly, and the left 6/6. The child was put under chloroform, and, through an incision made at the corneo-scleral junction, a little to the nasal side of the filament, the foreign body was successfully removed, though breaking into two pieces on account of its brittle structure.

From the pathological examination made by Dr. Shennan, of Edinburgh, and Mr. A. E. Shipley, of Cambridge, no confirmation was obtained of the presence of a parasite. Microscopic sections showed that the filament was mainly composed of stratified epithelium, with a little loose connective tissue and some melanine pigment. Discussion was invited as to its probable origin—e.g., in a congenital displacement of part of the epithelium from the anterior surface of the iris, or a capsulo-pupillary vestige.

Mr. W. H. H. Jessop gave a report of the Inter-

national Committee on the

UNIFICATION OF THE NOTATION OF VISUAL ACUITY AND OF THE MERIDIANS OF ASTIGMATISM.

The Committee, after consideration, came to the following conclusions:—(1) That the meridians of astig-matism should be measured and represented as the observer looked at the patient. (2) That the axeshould be measured and represented in the lower semi-circle of the trial frame. The numbering of the axes should start from the middle line of the face in each eye, and proceed downwards and temporalwards. The zero would therefore lie at the nasal end of the semi-circle, and 180° at the temporal end; 90° would be below and midway between these points. The Committee also agreed that for international test type, numbers should be used. Landolt's ring was also thought to be a suitable object. The unit of measure was an angle of r minute, and the figures were to be constructed on this unit. The types were to be constructed as regards size on arithmetical progression, and the standard distance at which they were to be seen should be 5 metres. The source of light was to be diffuse daylight, if possible, opposite the types, and not laterally.

FRANCE.

Paris, June 20th, 1989.

DEPOPULATION.

ALCOHOLISM is another plague worthy to be placed alongside tuberculosis. It threatens not only the health of the individuals who indulge in alcohol, but the future of the race.

The study of alcoholism is of recent date. It was a Swede, Magnus Huss, who, in 1852, was the first to draw attention to the evil effects of alcohol on the social life of peoples, and for the last thirty years it has been a live question in France.

Five kinds of alcohol may be found in beverages: methylic, ethylic, prophylic, butylic, and amylic alcohol. Ethylic alcohol, distilled from grain, tubers,

sugar-cane, etc., is almost exclusively used for consumption; methylic or wood alcohol is used for adulteration. Alcohol, even rectified and freed from impurities, is toxic in itself, as proved by Rabuteau in 1870 and later by Joffroy and Servaux.

The production of alcohol in France is very con-

siderable. The vine plantations cover in the aggregate 4½ millions acres, and the wine crop of 1908 exceeded 60 million hectolitres (hectolitre = 22 gallons). Beer forms the chief drink of the northern departments, attaining 300 quarts per head of the population, while 350 quarts of cider per capita are consumed in the north-west of Brittany.

The production of distilled alcohol, which was about 900,000 hectos per year some 60 years ago, reached the formidable figure of 3,656,000 hectos in 1900, and of this amount only about 180,000 hectos were exported; the rest was consumed in the country under the form of cognac, eau de vie, liqueurs, aperitifs,

and absinthe, and represent 15 quarts per head.

The French nation, says Prof. Courmont, is, without doubt, the nation which drinks the most alcohol. If, instead of calculating roughly the amount consumed per capita, abstraction were made of young children, sick people, total abstainers, it would be found that an adult Frenchman drink 100 quarts of alcohol at 100° per year!

In certain departments, as La Manche and La Normandie, Côte du Nord, Pas de Calais, men, women, and children—babies, even—take a considerable amount of alcohol daily.

The rank that different countries take as regards the consumption of alcohol per head of the population appear in the following statistics, drawn up in 1806:-

France			14	litres	19.
Belgium	•••	• • • •	10	,,	59.
Italy		•••	10	,,	22.
Germany	• • •	•••	9	,,	34.
England	• • •	• • •	9	,,	23
United States	• • •		6	,,	07
Sweden	• • •	• • •	4	,,	39.
Norway			3		31.

Consequently, France takes the lead, which is not very astonishing, as the law allows one café to every 80 inhabitants, while in the large cities in nearly every third house there is a drinking-shop.

Is alcohol a food? The question was answered in

the affirmative by Duclaux, and later by Chauveau, Atwater, and Benedict.

No doubt a portion of the alcohol ingested is utilised, and in a purely scientific point of view it may be admitted as a food, but one that should be used with prudence, for two reasons: it is an expensive food and a poison.

The deleterious effects provoked by the excessive use of alcohol are well-known, and might be résuméd thus: mechanical irritation of the digestive tract, dehydration of the tissues, dilatation of the capillaries, fatty degeneration, peri-vascular sclerosis.

The lesions produced are very complex in their

- (1) Digestive organs: acute or chronic gastritis, intestinal catarrh, cirrhosis of the liver, fatty degeneration of the liver, chronic peritonitis, pancreatic diabetes.
- (2) Heart and vessels: fatty degeneration, arteriosclerosis.
- (3) Respiratory tract: pharyngitis, laryngitis, predisposition to pneumonia, gangrene, tuberculosis.
- (4) Nervous system: central cerebral derangement, meningitis, atheroma of the cerebral arteries, peripheric neuritis.

From a clinical point of view, acute alcoholism may produce delirium tremens or epileptic seizures (absinthe drinkers).

The relation between alcoholism, or more particularly absinthism, with criminality and lunacy, is firmly established. The increase of crime and mental disease in France is evidently due to the increase in the consumption of alcohol.

In 1861 the number of lunatics in the different asylums in the country was 2,902; in 1896 the total number was 22,671, of which 50 per cent. were

absinthe drinkers, and in this proportion the femalesex formed a large minority.

The question of repercussion of chronic alcoholism on the race has been proved beyond all doubt by competent authorities, and the principal hereditary effects are: dipsomania, troubles of the nervous system, anatomical malformations.

The children of alcoholic parents feel from the age of 15 or 20 an innate want of alcohol, and become alcoholic in their turn. The cellular elements demand their natural simulant, like those who are addicted

to morphia.
"Your father drank," says the proverb, "and you will drink; you will drink more than your father, and your children more than you."

The cerebral troubles are manifested by epilepsy, hysteria, convulsions, neurasthenia, absence of moral

stability, violence of character, loss of mental balance. The congenital lesions due to alcoholism are numerous: malformation of the limbs or organs, infantilism, hydrocephalus, idiocy, essential epilepsy, etc.

Dr. Legrain, who has for years fought the good fight against alcoholism, studied the history of 215 alcoholic families, representing 508 individuals. The first generation had a large number of stillborn children or deaths in infancy, while 168 were degenerated both physically and mentally. In the second, all the families had degenerated, whilst of the third there only remained 17 individuals, almost all idiots. FURUNCULOSIS.

Furunculosis, as is well known, is a lesion of the pilo-sebaceous apparatus provoked by staphylococci. Dyspepsia, diabetes, arthritism, local irritation are secondary causes.

The local treatment consists in sulphur baths:-Monosulphide of sodium, 1 oz.

Carbonate of soda, 6 oz.

Chloride of sodium, 3 oz.
As soon as a boil appears it may be touched with tincture of iodine. If suppuration has set in, an inci-sion is made, and, after extraction of the pus, the cavity is filled with:

Sublimed sulphur, Camphor, } equal parts,

Glycerin, q.s. while a plug of glycerin is placed over the orifice. The general treatment consists in ingesting a mixture

of honey and sulphur :-

Sublimed sulphur, 5 dr. Camphor, 10 gr. Honey, 1 oz.

A teaspoonful before each meal. After each meal, one of the following wafers:

Calcined magnesia, 11 dr. Lactose, 11 dr. Bicarb. of soda, 1 dr. Carbonate of lime, 1 dr. No. 12.

#### GERMANY.

Berlin, June 20th, 1909.

AT the Verein für Innere Medizin a discussion on Hr. Heubner's paper on

THE DIFFERENTIAL DIAGNOSIS OF THE ACUTE AND EXANTHEMATOUS DISEASES

took place.

Hr. Plehn said that he had found patients with a measles rash, who a few days later developed a scarla-tina rash, which was followed by an ordinary scarlatina. He had got the impression that such cases were-scarlatina with an atypical exanthem. In any case he had seen cases in which measles and scarlatina developed simultaneously. He had also seen true re-lapses after scarlatina, with a typical course of the disease followed by desquamation. He had also seen repeated attacks of scarlatina in the same individual after the lapse of years. These often ran an atypical course, especially as regarded the rash. As regarded the 4th and 5th disease, he was sceptical.

Concerning the differential diagnosis between measles

and scarlatina, which was sometimes very difficult, the diazo-reaction in measles never really failed, whilst in scarlatina it only showed itself in very bad cases. A distinction between the injection exanthem of the injected cases, and the scarlatina exanthem was sometimes scarcely possible.

Hr. Fuld expressed regret that a plan that he had worked out for biological examination had not been carried any further by Hr. Heubner after it had failed in one case.

Hr. Citron remarked in regard to the negative results that had been obtained with antigens that French inquirers had always obtained positive results with streptococci from scarlatina cases. Schleussner had had like results without being aware of the labours of the French inquirers. Whether extract from measles streptococci also had a positive result in scarlatina required further investigation.

required further investigation.

Hr. Heubner, in reply to Plehn, said that he had never seen a prodromal rash in scarlatina, he considered it a double exanthem. He had several times recently seen a kind of rötheln and measles occurring simultaneously. He agreed with Plehn in regard to the diazo-reaction in measles; but the reaction was seen not very rarely in not very bad cases of scarlatina. Sometimes it was not possible to distinguish a serum exanthem from a scarlatina rash.

According to the Deutsche Med. Zeitung, Prof. Paul H. Römer makes the announcement that his new method of using tuberculin for diagnostic purposes consists in injecting small doses of tuberculin solution into the skins of animals, and then, when the animals have become ill, measuring with great exactness the infiltration that has taken place.

The Prussian Minister for Medical Affairs makes the announcement that owing to the increased cost of preparing the curative serum for cerebro-spinal meningitis, a charge will in future be made of 2 m. per ccm., as an aid in partly covering expenses.

#### AUSTRIA.

Vienna, June 201h, 1909.

HIPPURIC ACID AND PAIN IN MICTURITION.
PINELES gave an exhaustive account of his clinical examination of 110 cases, which came under his notice complaining of great pain in passing urine without any of the real phenomena or other vesicle trouble, such as sudden attacks of gout or tophi being present.

He divided these cases into three groups: The first comprising 46 of the cases occurring in females at the climacteric period, and having all the symptoms of pains in the arms, hands, shoulders, back, etc. This form is relatively frequent, and seems to be due to the involution and alterations occurring in the genital apparatus. The second group comprises 19 of the cases, and occurs mostly in the senile state. A large number of these were present in elderly females associated with the painful sensations of the climacteric, and may possibly be due to retarded involution in the aged. The third group comprehends individuals suffering from functional or nervous diseases, among which were four females afflicted with myoma, endometritis and oophoritis, and twelve males with functional disturbance of the genitals and imperfect vita sexualis. Thus we may conclude that two-thirds of the whole cases of the so-called painful micturition had their pathological origin located in the genital apparatus. Pineles was inclined to isolate this disease under the name of genital pseudo-gout occurring in three groups under the terms climacteric, senile and

#### NATURAL FEEDING OF INFANTS.

Jaschke followed with a minute description with the physiological technique of the natural feeding of infants. He arranged his subject into regular periods of teeding, and considered three or four hours a sufficient interval, with six or eight hours' rest at night.

The best method he thought of controlling the weight and growth of the child was by regularly weighing. A rapid increase of weight would point to overfeeding, which should be carefully guarded against. The quantity taken at one meal when fed at the breast can only be measured by weighing before and after. The first food after birth will depend very much on the vigour and strength of the infant, but as a rule, it should never be put to the reast during the first day.

The cause of many evils in the child's history depends very much on the irregular practices at this period of its life. In many cases, however, the child is placed at a disadvantage with an abnormal mammilla, such as the narrowing of the channels requiring greater force than the infant possesses to empty the organ, and in consequence the breast is never entirely cleared of the lacteal secretion. To overcome this difficulty the milk should be drawn with an exhauster and given to the child. The time that an infant should be allowed to remain at the breast varies from 15 to 25 minutes in a healthy child, but may be extended in a feeble one. Where the milk secretion is insufficient, four or five times exhausting with a breast pump may increase its flow in simple cases, but more difficult ones must be treated with Bier's congestion method. For a depressed nipple either the exhaust pump or massage should be practised.

# FROM OUR SPECIAL CORRESPONDENTS AT HOME.

#### SCOTLAND.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN. This Section of the Royal Society of Medicine held its annual provincial meeting in Edinburgh on the 18th inst. The proceedings were inaugurated by a luncheon given by the local executive committee, and thereafter the meeting proper was held in the Sick Children's Hospital. A number of interesting cases were demonstrated. Dr. George Gibson showed a case of patent ductus arteriosus, Mr. Scot Carmichael a case of Sprengel's deformity of the scapula with a a case of Sprengers deformity of the scapula with a curious webbed condition of the skin of the shoulder, and Mr. Harold Stiles a series of surgical cases of great interest, including examples of transplantation of the ureters into the pelvic colon for epispadias in the female, cholecystenterostomy for obliteration of the bile duct from injury, and sub-periosteal removal of the whole diaphyses of the long bones for tuber-culous osteomyelitis. In connection with the last group of cases, Mr. Stiles pointed out that if the cases were operated upon early enough, before the perios-teum was involved, recurrence did not take place. When the diaphysis was removed the epiphyseal cartilage was left in situ, and from it, and the periosteum, a new diaphysis was formed. After an interval for tea, and the inspection of a museum which had been got together, the meeting resumed its sederunt for the purpose of hearing papers. Among those read were notes on the treatment of hyperpyrexia in children by Dr. Burnet, a method of estimating the vitality of the leucocytes, and a comparison between the toxicity of the blood serum in rheumatism and chorea, by Dr. McAlister, a record of a case of irreducible intussussception treated by lateral anastomosis, a case of acute leukæmia with atypical cells in the blood, by Dr. Lapage. The scientific proceedings, which in the end had to be somewhat abbreviated for lack of time. were brought to a close shortly before 7 o'clock, and later in the evening the members of the Section, with a number of invited guests, dined together in the Caledonian Hotel. Dr. George Gibson, who presided, gave the toast of the evening, "The Health of the Society for the Study of Disease in Children," to which Dr. George Carpenter replied, urging that a which Dr. George Carpenter replied, urging that a larger number of Edinburgh men should join the Society than was the case at present. The toast of "The Guests" was proposed by Mr. Stiles, and replied to by Dr. Norman Walker. The sectional proceedings were presided over by Dr. George Carpenter, London, and among those who attended the meeting from a distance of the property of the process of t distance were Drs. Hugh Lett, Spriggs, Sutherland. Tubby, Sydney Stephenson (London), Dr. Macalister (Liverpool), Dr. Lapage (Manchester), Dr. Mackerra (Aberdeen), Dr. Stalker (Dundee). A number of local medical men, not members of the Society, were also present at the meeting. On Saturday a golf match

was arranged for the members present.

EDINBURGH UNIVERSITY.—RESIGNATION OF PROFESSOR JOHN CHIENE, C.B.—At the last meeting of the University Court an application from the Professor of

Surgery for permission to retire was granted, to take effect as from August 31st next. Professor Chiene has resigned on account of failing health; he obtained leave of absence in the end of last year, but the rest from work has not done him sufficient good to warrant him resuming active work in the University. Professor Chiene was appointed successor to the late Professor Spence in 1882, so that he celebrated his "silver wedding" as Professor two years ago. On that occasion he addressed his class on things of bygone days, and the address, subsequently published under the title of "Looking Backwards," was full of interesting reminiscence and entertaining anecdote. Professor Chiene was an Edinburgh student; he was a good athlete in his day, and has always manifested a keen desire to encourage outdoor sports among the students. He graduated with Honours in 1865, and among his masters he numbered Goodsir, Syme, and Joseph Lister. His whole life and energies have been devoted to carrying out Goodsir's dying injunction to him—"Teach the students, Mr. Chiene"—and he has let no professional claim come between him and his selfimposed task. During the South African War he was Consulting Surgeon to Her Hajesty's forces, and for his services he was made a C.B., and was mentioned in despatches. He is an LL.D. of Glasgow University, and has held many other important offices. John Chiene has been much beloved by his students, to whom his geniality, his hospitality, and his untiring devotion to their interests has greatly endeared him, and his resignation will cause a blank in the medical faculty which will be difficult to fill.

GLASGOW UNIVERSITY.—Under the will of Dr. J. Hall, M.D., St. John's Wood, London, who left estate of the gross value of £88,366, the Senatus of the University of Glasgow (of which Dr. Hall was a graduate) will benefit to the extent of about £35,000, This has been left to found the "Hall Tourist England". This has been left to found the "Hall Tutorial Fellow-ships" in surgery, medicine, and midwifery, to be awarded after examination to graduates of not more than five years' standing. Each Fellowship is to be of the value of £200 per annum, and there are to be as many of these as the income of the trust funds will admit of, any surplus to be applied to the purchase of teaching appliances or prizes. The Fellowships are to be held apart from any other endowment or scholarship, and the holders must reside within three miles of the University, and are to devote their whole time to the practical instruction of the students under the direction of the professors, and may not engage

in any private practice or tuition.
RUCHILL HOSPITAL.—The affairs of Ruchill Hospital are again to be dragged into publicity through the decision of the Glasgow Town Council to accept and act upon a petition signed by 18,000 citizens for an independent inquiry "into the administration of Ruchill Hospital from the date of the Local Government." ment Board inquiry up to the present date" by a committee of citizens "drawn from the following bodies: three from the Faculty of Physicians, three from the Faculty of Procurators, three from the Merchants' House, and three from the Trades Council, with a neutral chairman, such as Sir Donald MacAlister or Dr. Robert Gourlay." It is to be hoped that this inquiry will bring the apparently interminable disputes about Ruchill Hospital to an end.

PROFESSOR CLELAND, GLASGOW.—Professor Cleland, who for thirty years has occupied the Chair of Anatomy in the University of Glasgow, has intimated his resignation. His resignation was not expected. It is prompted by a desire for a well-earned rest, and not by reasons of health. The only name that has reached us as a candidate for the vacant chair is that of Professor Buchanan, whose "Manual of Anatomy" in the "University Series" is so well known.

#### BELFAST.

QUEEN'S COLLEGE.—At a meeting of the Better Equipment Fund held last week, it was stated that a sum of £5,100 had been invested in Corporation Stock, and that this had been ear-marked for the purchase of an athletic ground. There has been great difficulty in finding a suitable ground, as estate owners

in the suburbs of the city show a tendency to "hold up" their land for building purposes, but it is to be hoped that some of the wealthy and influential merchants on the committee of this fund will give the matter serious attention, and that soon the students may enjoy their games on a good ground of their own.

ROYAL MEDICAL BENEVOLENT FUND.—The annual

meeting of the Belfast and County Antrim Branch of the Royal Medical Benevolent Fund of Ireland was the Royal Medical Benevolent Fund of Ireland was held in the Medical Institute, Belfast, on Friday, June 18th, the President (Professor Johnson Symington, F.R.S.) in the chair. The report showed that a total sum of £164 had been raised during the year, including £6 11s. from the Belfast Medical Students' Association. There are still some 70 or 80 members of the profession in Belfast who give nothing, and in the county there are only 40 subscribers among 200 practitioners. Dr. Richard Purdon, the late hon. secretary, said that on the whole Ireland did not do badly in the way of medical charity. In England there were 25,000 medical men, and their contributions to the British Medical Benevolent Fund amounted to £1,700, or 1s. 4d. per head. In Ireland they had 3,000 medical men, and their contributions were £541, or an average of 3s. 7d. per head. There was no reason why they should not improve upon this. On the motion of Dr. Gaussen, seconded by Dr. Wadst worth, Professor Symington was re-elected President, and on the motion of Dr. Calwell, seconded by Dr. Maguire, the committee was re-appointed, and also the hon, secretary, Dr. Victor Fielden.

TYPHOID AND WAKES IN LONDONDERRY .- At the Derry Petty Sessions last week a woman was summoned and eventually fined for holding a wake for two nights on the body of her husband, who had died of typhoid. It appeared that the family refused to let the man go to hospital, as was advised, and that after his death a notice was sent warning the widow that a wake must not be held. In spite of this the wake was held for two nights, hence the prosecution. The de-fendant had rendered herself liable to a penalty of £5, but as she was very poor the magistrates let her off with a penalty of rs and a magistrates let her

ff with a penalty of 5s. and a warning.
STRABANE DISTRICT NURSING SOCIETY.—The fifteenth annual meeting of this society was held last week, the Duchess of Abercorn presiding. The report stated that little or no good seems to have resulted from the Tuberculosis Exhibition and the lectures in connection Tuberculosis Exhibition and the lectures in connection with it. The old state of things continues, notwithstanding the advice of the visitors of the Women's National Health Association, who have gone through all the town. One thing strikes one as remarkable in the report of the meeting, and that is that no medical man seems to have taken part in it. If such a society is properly worked it ought to be of the greatest help to the profession, and if it is not so, the local influence of the profession ought to be sufficient to have things altered things altered.

MEDICAL GOLF .- The annual competition for the Lindsay Cup was held last week on the Ormeau Golf Club's links at Belfast, and resulted in a win for Mr. Andrew Fullerton, F.R.C.S.I.

#### LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

SICKNESS AFTER ANÆSTHESIA

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,-Dr. Blumfeld has put practitioners under an obligation by his extremely helpful paper under the above heading in your valuable journal. I find nothing to criticise in it; but I think it leaves out a small, but not unimportane, class of cases to which I should like to refer. These are cases in which nausea and vomiting seem mainly or entirely due to the swallowing of blood and mucus during removal of adenoids. My attention was first drawn to such cases about twenty years ago, when, as a very junior practitioner, I had charge of a patient, a boy, et. 15, under a leading surgeon of the day. The operation was prolonged, and much blood and dibris passed into the stomach.

The boy complained of extreme nausea for more than 48 hours. He could take no food; retching was frequent, but only a few mouthfuls of bloody fluid were got rid of with each effort. In all such cases it has since been my practice to administer a simple emetic with plenty of warm water; and to repeat this if not satisfied that the stomach is thoroughly cleared of blood. I find that this treatment almost invariably puts an end to the nausea; and if, whilst giving plenty of milk and soda water, a saline dose is administered, all the symptoms rapidly vanish, and convalescence is at once established. It is evident in many of these cases that the nausea is mainly due to mental causes. The patient's horror of the blood in the stomach 'makes him sick."

I am, Sir, yours truly, AN OBSCURE PRACTITIONER.

June, 18th, 1909.

PREVENTION OF DENTAL CARIES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.
SIR,—In every department of preventive medicine Six,—In every department of preventive medicine the aim should be to get at prime causes, and this applies as strongly to dental disease as to any other. The prime determining causes of dental caries are, first, innate structural defects in the teeth; second, crowding and irregularity due to small, ill-formed jaws; and, third, septic conditions of the mouth. Well-formed enamel is as hard as limpid quartz; the worst formed is chalky in texture; and patches of illcalcified tissue of infinitely varying quality are found in all imperfect sets of teeth. Given first-rate enamel and well-shaped jaws, and it is astonishing the amount of neglect the teeth will endure without harm, whereas the highest skill and the most assiduous attention will not save organs the tissues of which are inherently defective. These facts do not seem sufficiently recognised in Mr. H. R. F. Brooks's excellent Inaugural Address at Birmingham, which you report to-day. If we could put an end to constitutional discounting time to the saves of content which I have eases giving rise to the causes of caries which I have named, dental decay would be enormously diminished at once. Among these diseases I should give a first or osseous appendages, they always seem as ill-formed as the bones in rickets. Further, the jaws are often ill-formed and ill-shaped in this disease, whilst the secretions of the mouth during childhood with rickets are mostly foul to a high degree. Now rickets is a disease of malnutrition. Its main cause is improper feeding. It is easily preventable by simple measures, and its prevention would prevent dental decay. If one wants to see full illustration of this fact, it may be found in an examination of the mouths of the children of typical well-fed Scotch or Irish peasants, and rickety, narrow-chested wastrels that swarm in the slums of our great towns. Inferior teeth are only one manifestation of general physical inferiority; the defect can be prevented and should be dealt with by measures directed to improvement of the whole organism.

I am, Sir, yours truly, M.R.C.S., L.D.S.

June 16th, 1909.

THE EMOLUMENTS OF CHRISTIAN SCIENCE. To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—The letter of Dr. Duke printed in your issue of the 16th inst. has reference to a matter of fact, not to a matter of opinion. In these circumstances to permit the person attacked to reply is simply a question of fairness, and I think you will extend this courtesy to us in this instance as you have done in the past.

It is to be hoped that Dr. Duke's readers are better acquainted with the passage from Matthew which he quotes than he appears to be, though it must be confessed that if they are it will not exalt their opinion of his logic. It is quite true that Jesus commanded his disciples to "Heal the sick, cleanse the lepers, raise the dead, cast out devils": that is why Christian Scientists are insisting to-day on another of his commands to preach the Gospel and to heal the sick, and insisting that these two clauses are inseparable. It is also true that he added to these words the complement, "freely ye have received, freely give," but it is surely equally plain that the "freely" referred to the fact that the healing was to be without stint. Dr. Duke seems to have a suspicion of this, for he omits the further injunction of Jesus to the dis-ciples to make their home with those whom they helped, and he leaves out the terrible words in which Jesus wound up His charge to the apostles with a denunciation of those who failed to provide for them.

Between the Palestine of the first century and Western Europe of the twentieth century there is a great gulf fixed. It is no longer possible for those who are striving to heal the sick to enter and abide in the houses of those whom they are helping, providing themselves with neither gold, nor silver, nor scrip, nor coats, nor shoes, nor yet staves; and so some recompense, of a nature more adaptable to the complex civilisation of to-day, has been substituted by the world for this primitive method. For, with all deference to Dr. Duke, the world does recognise the justice of Jesus saying that "the workman is worthy of his meat" and "the labourer is worthy of his

The old system did not die in a day. The guesten halls of the old monasteries provided some such hospitality to travellers, and in these monasteries, at first in connection with these guesten halls, there came into being the germ of the hospital system. That is into being the germ of the hospital system. That is why the hospital was first known as the hotel Dieu. Anybody who really knows anything about the practice of Christian Science knows that the fees taken by Christian Science workers are, at all times, of the smallest description, and are reduced to practically nothing at all—very frequently absolutely to nothing at all—to meet the means of the patient. Perhaps, however, the clearest rebuke to Dr. Duke's argument is contained in St. Paul's words to the Church in Corinth, "If we have sown unto you spiritual things, is it a great thing if we shall reap your carnal things?"

I am, Sir, yours truly, FREDERICK DIXON.

June 18th, 1909.

[We have printed the above, as we wish to be absolutely fair to everyone, no matter how much we may differ from his opinions and beliefs. It seems to us, however, that Mr. Dixon has failed to refute, or even remotely to answer, Dr. Duke's argument, which we take to be as follows: The "Christian Scientist" take to be as follows: The "Christian Scientist" healer undertakes to cure disease "by prayer and poultice." Will he be paid by results, or will he follow the advice given by the Master (Matthew x., 8, 9), "Heal the sick; freely ye have received, freely give." Mr. Dixon has written many words, but, so far as we can gather, he admits that "Christian Science" healers receive payment. No amount of excuse or explanation can get behind that fundamental even on Mr. Dixon's own showing, in his facts, and we are at a loss to understand how the latter gentleman can attempt to discuss the matter with an appeal to fairness.

The element of money-making is bound to cast a slur upon any semi-philanthropic or quasi-religious scheme. It is no more necessary for a "Christian Scientist" to make money out of his grotesque per-suasions and beliefs than it was for the early Apostles to demand money for their ministrations. Reduced to its ultimate analysis, "Christian Science" healing is a form of false medical practice, constituting, when money is made out of it, the offence of obtaining money under false pretences. It is to be hoped the Church of England will keep away from this more than questionable thing.—ED. MED. PRESS AND CIRCULAR.]

Cork Medical and Surgical Society.

At the recent annual meeting of the Cork Medical and Surgical Society the following officers were elected for the Session 1909-10:—President, Professor D. T. Barry; Vice-President, Dr. J. Booth; Honorary Treasurer, Dr. C. B. Pearson; Honorary Librarian, Dr. E. Murphy; Secretary, Dr. J. T. O'Connor. A Council of seven members was also appointed.

#### OBITUARY.

FREDERICK NUTCOMBE HUME, M.R.C.S., L.R.C.P.

WE regret to record the death, on June 14th, of Dr. Frederick Nutcombe Hume, Medical Superintendent of the Metropolitan Asylums Board's North-Western Hospital, and Major in command of the and London Division of the Royal Army Medical Corps (Territorial Forces). Dr. Hume had seen service as a surgeon in no less than four campaigns in the Balkans. The mourners at the funeral included, in addition to members of the family, Professor Smith, Mr. Cole, and Mr. A. Boden, members of the Metropolitan Asylums Board; Mr. Duncombe Mann, clerk to the Board; Dr. A. H. Downes, of the Local Government Board; Dr. G. F. McCleary, Medical Officer of Health for Hampstead; Colonel Andrew Clark, Colonel Magill, C.B., Colonel W. R. Smith, Major Ballard (representing Major-General Vesey-Dawson, C.V.O.), Major Irwin Palmer, Captain Caldwell Smith, Captain Coffield, and Lieutenant A. J. Martin, brother officers of the deceased and Drs. G. Pugh, H. Cuff, C. E. Matthews, Prausnitz, McCombie, Bruce, Caiger, Goodall, and Wilcox.

#### WILLIAM ALLINSON M'LACHLAN, M.D.GLASG.

WE regret to announce the death of Dr. W. A. M'Lachlan, at his residence, Dumbarton, after a long and painful illness. Dr. M'Lachlan, who was in his 61st year, was laid aside by illness about a year ago. In early life he assisted his father, the late Mr. David M'Lachlan, master slater and plasterer, and at an early age he successfully founded a branch of the business in Dumbarton. A few years later he became a medical student, and after a meritorious career graduated in 1874. After a brief period as Medical Officer to the parish of Tarbolton he returned to Dumbarton and rapidly built up an extensive practice by reason of his business habits, ability, and industry. For many years he was an active member of the Town Council, and served as a magistrate. For fully twenty years he was Medical Officer to the parish of Cardross. He was also Surgeon-Captain in the local Artillery Volunteers. Dr. M'Lachlan was the author of numerous contributions to lay and medical journals, and he was a graceful and fertile writer on poetical subjects. In 1874 he made several experiments to demonstrate that diphtheria began as a local affection in the throat, and that the constitutional symptoms followed the local infection.

## SPECIAL ARTICLES.

## STANDARDS OF PURITY FOR FOODS.

At the recent meeting in London of the Seventh Congress of Applied Chemistry, the section dealing with Bromatology devoted considerable attention to the advantages and disadvantages of legally binding standards of purity for foods. Papers were read by Continental and British observers on methods of analysis of many of the more important articles of food.

The paper by Mr. C. G. Moor and Mr. William Partridge, while dealing with a greater number of foods than we have space to mention here, dealt in particular with the important subjects of standards for milk and for infants' food, and hence we have considered it of sufficient interest to reproduce here some of the suggestions made by the authors.

Their paper was prefaced by introductory remarks indicating that, in the authors' opinion, the application of standards in this country, although such application as at present exists has been limited to a very few articles, has uniformly produced a beneficial result.

They considered that the adoption of standards of purity was of advantage to the public because it insured them against gross adulterations which had been found to be prevalent in the past, when no standards of any kind were in operation.

So far as the producer or trader was concerned, the authors believed that the adoption of standards would tend to put a stop to the unfair competition due to the sale of adulterated articles, and moreover that it was only fair to traders that they should, by the free and full publication of standards, know precisely what was expected of them. Standards might bepublished, which for a given period might be tentative only, in order that before they were finally incorporated into an Act, they might be discussed and revised if they were found either too stringent or too lenient.

THE MEDICAL PRESS.

From the point of view of those who have to apply the Foods and Drugs Acts, the adoption of standards appeared to the authors to be likely to conduce touniformity of administration.

At the present time each analyst when reporting on any sample sent in to him had to form his own independent opinion on it, the result of which was that certain articles were allowed to pass in some districts which were condemned in others.

The adoption of standards found favour in the United States and in the Commonwealth of Australia, and was also a matter of earnest consideration in other countries.

In dealing with the subject of infants' fcods, the authors pointed out the necessity for special legislation to insure that their composition should be suitable, and that the directions given for their use should specify what quantity is intended to be used in a period of 24 hours, and that the claims made for them should be true in substance and fact. The authors pointed out that recommendations to secure these highly important points had been published by them some years ago, and that the recent regulations of the Victorian Government embody the same recommendations almost word for word.

In dealing with the subject of milk, the standard which was first fixed for use in this country as a minimum percentage of fat was 2.5, it was later on raised to 2.75, and is at present fixed at 3.0 per cent. In many other countries the standard was 3.5, but the difficulty in raising it above the figure now fixed was that there are a certain number of milks which are naturally no higher than 3.0 per cent. in fat.

Such natural poorness is however rare, and the suggestion of the authors was, that the authorities in each district should regularly publish the figures obtained by the Public Analyst on all the milks analysed, with the name of the vendor. In this way they considered that it would become known that the majority of vendors regularly supplied a good and genuine milk, and that the public would learn to discriminate between them and the vendors who make it a regular practice to impoverish milk intentionally. In the authors' judgment the force of public opinion would cause the practice of this unfair form of competition to die out, and that in this way a general improvement in our milk supply would result.

#### REVIEWS OF BOOKS.

INFECTIOUS DISEASES. (a)

In the preparation of the second edition of this book, Dr. Goodall has been deprived of the assistance of his fellow-worker, Dr. John Wichenford Washbourn, but the work still remains as a monument to the wide-clinical experience and clear judgment of his former colleague. In the present edition chapters have been added dealing with "Plague," "Cerebro-Spinal Fever," and "Glanders," and in other ways the book has been revised in accordance with the advance in our knowledge of fevers in general. In its present condition the work forms an admirable text-book of the infectious fevers, in which the teaching is sound and clearly expressed. The illustrations add considerably to the usefulness of the book, and are very well reproduced, many of them being taken from photographs of actual

We congratulate Dr. Goodall on the result of his (a) "A Manual of Infectious Diseases." By E. W. Goodall, M.D. Lond. and J. W. Washbourn, M.D.Lond. Second Edition. Revised and Enlarged by E. W. Goodall. 8vo, pp. xii. and 426, and 33 Plates. London: H. K. Iewis. 1908.

labours, and feel that we may assure him that it will not be found unworthy of association with the name of his late colleague, Dr. Washbourn.

THE READING PATHOLOGICAL SOCIETY. (a) THE Reading Pathological Society was founded in July, 1841, and now enjoys the senior position as regards age of the various pathological societies of England. The Pathological Society of Dublin was founded some three years before, but in 1882 it ceased to have an independent existence, being then merged in the Royal Academy of Medicine in Ireland as the Pathological Section. Though in the year 1898 the two medical societies of Reading, the Pathological and the Medico-Chirurgical, united, still the former society seems to have been able to preserve in the union its identity. Perhaps no branch of medicine has undergone more development during the past seventy years than that of pathology, and the history of this years than that of pathology, and the history of this development, as chronicled in the minutes of the Society before us, makes most interesting reading. It seems strange to think that at this Society, little more than sixty years ago, the view could have been held that fever, cholera, and typhus had one origin, and were "merely modifications of the same poison, the effects depending on the dose and the peculiarity of constitution, habits, etc., of the individual." We regret that Dr. Hurry has not enlarged more on the story of this development, and given us more of the individual views of the members of his Society. The volume, as presented, will be, no doubt, of great interest to members of the Society but it makes little more than a dry catalogue for the general reader. The short biographical notices of some of the members are the most interesting part of the book, and this more especially as they were mostly the ordinary workmen of our profession, those whose record is so interesting, yet so soon lost. The book is illustrated by many portraits, which are very well reproduced. We must congratulate the Society in having its annals presented in such an attractive dress.

#### NEW BOOKS AND NEW EDITIONS.

THE following have been received for review since the publication of our last monthly list:—

EDWARD ARNOLD (London).

Further Advances in Physiology. Edited by Leonard Hill, M.B., F.R.S. Pp. 440. Price 15s. net.

The Sanitary Officer's Handbook of Practical Hygiene. By C. F. Wanhill, Major, R.A.M.C., M.R.C.S.Eng., L.R.C.P.Loud., D.P.H., and W. W. O. Beveridge, D.S.O., Major, R.A.M.C., 5s. net.

M.B., C.M.Edin., D.P.H.Cambridge, D.S.O., Major, R.A.M.C., M.B., C.M.Edin., D.P.H.Cambridge, F.C.S. Pp. 150. Price 5s. net.

BALLIERE, TINDALL AND COX (London).
The After Treatment of Operations: A Manual for Practitioners and House Surgeons. By P. Lockhart Mummery, F.R.C.S.Eng., B.A., M.B., B.C.Cantab. Third Edition. Illustrated. Pp. 251. Price 5s. net.
High Frequency Currents: Their Production, Physical Properties, Physiological Effects, and Therapeutical Uses. By H. Evelyn Crook, M.D., B.S.Lond., F.R.C.S.Eng. Second Edition. Illustrated. Pp. 232. Price 7s. 6d. net.
The Re-education of Self-Control in the Treatment of the Morphia Habit. By Oscar Jennings, M.D.Paris. Pp. 31. Price 1s. net.

John Bale, Sons and Danielsson. Ltd. (London).
The Medico-Chirurgical Series. No. 1. The Practice of Amesthetics. By Rowland W. Collum, L.R.C.P.Lond., M.R.C.S.Eng. General Surgical Technique. By H. M. W. Gray, M.B., C.M.Aberd., F.R.C.S.Edin. Edited by James Cantile M.A., M.B., C.M.Aberd., F.R.C.S.Eng. Pp. 382. Price 10s. net.
How to Cut the Drug Bill. By G. Herbert Hart, M.D. Pp. 47. Price 2s. 6d.
Polydore Barnes Co. (New York).
Medical and Surgical Report of the Presbyterian Hospital in the City of New York. Vol. 8, December, 1908. Edited by John S. Thacken, M.D., George Woolsey, M.D. Pp. 371.

Cassell And Co., Ltd. (London).
The Open-Air Treatment of Pulmonary Tuberculosis. By F. W. Burton-Fanning, M.D.Cantab, F.R.C.P.Lond. Second Edition. Pp. 184. Price 5s.

#### The Royal Society of Arts Conversazione.

The annual and very popular conversations will be held, by permission of the Trustees of the British Museum, in the galleries of the National History Museum, South Kensington, on Tuesday evening next. the 29th inst.

The reception, by Sir William H. White, K.C.B., F.R.S., Chairman, and the other members of the Council, will be held in the Central Hall from 9 to 10 p.m. All the rare and beautiful exhibits of the Natural History Museum will be on view. Concerts in varieties sections will be given, and light refreshments supplied to visitors free of cost.

<sup>(</sup>a) "A History of the Reading Pathological Society." By Jamieson R. Hurry, M.D. 8vo, pp. 179, with 10 Illustrations. London: John Bale, Sons, and Danielsson, Ltd. 1909.

#### News in Brief. MEDICAL

#### Trinity College, Dublin

During Trinity Term, 1909, the following candidates for the Diploma in Public Health passed the examinations indicated:—Part I.—Charles D. Myles. Part II.—Charles D. Myles and Dudley F. Torrens.

The following passed the Final Medical Examination, Part II., in Medicine:—Ralph T. St. J. Brooks and David Duff (passed on high marks), Thomas A. Hughes, Eric J. Powell, Victor B. Kyle, George E. Craig, Frederick A. Anderson, John W. Flood, Cecil P. Smyly Craig, Frederic Cecil P. Smyly.

#### An Unqualified Chemist.

WHILST investigating the death of a carpenter's baby, the Hackney Coroner, on the 12th inst., learnt of the existence of a chemist's shop kept by a lady. The baby had a cold, and the mother purchased medi-cine at the shop referred to.

Mrs. Mary Ann Brierley, of Wick Road, the widow of a carman and contractor, said she was the keeper of the chemist's shop. She was not really a chemist, but was "just as good as one, as she went up for her examination and just failed."

Continuing, witness said the business carried on was not really a chemist's, as she did not sell poisons. She did sell camphorated oil, but only in pennyworths, never in quantities to harm. Possibly she sold the medicines given to the baby—a cough mixture and ipecacuanha wine, because it was asked for.

The Coroner: Of course, if she prescribed or sold

poisons something could be done, but there is no law

to prevent a woman selling herbs or harmless drugs. Dr. Alfred Stanhope Dawson said death was due to broncho-pneumonia. Far from doing any good, ipe-cacuanha was one of the worst things to give. The Coroner (to Mrs. Brierley): You run a great

The Coroner (to Mrs. Brierley): You run a great risk in giving medicines to sick children, and in the next case I should advise you to recommend a doctor

The jury returned a verdict of "Death from natural

#### Dr. Bell Taylor's Will.

DR. BELL TAYLOR, of Nottingham, has by his will left £5,000 each to the British Union for the Abolition of Vivisection, the London Anti-Vivisection Society, the British Committee of the International Federation for the Abolition of the State Regulation of Vice, the National Anti-Vaccination League, and the Royal Society for the Prevention of Cruelty to Animals; the gift to the last named society is conditional on the society within three years (or such extended period as the executors may allow) procuring the passing of an Act limiting the load which any horse or other animal may be compelled to draw to a weight bearing a certain proportion to the weight of the animal. In the event of the condition not being fulfilled, the legacy shall fall into residue for distri-bution among the other four societies named in equal The testator also directed that all his animals and birds should be kept in comfort as long as they shall live. The estate is of the gross value of £160,000, the net personalty being over £95,000.

#### The "Sanitas" Company.

At the annual meeting of this company, held at their works, at Limehouse, on the 16th inst., Mr. C. T. Kingzett, F.I.C., F.C.S., in the chair, attention was directed to some experiments lately carried out by certain bacteriologists accentuating the value of Sanitas Fluid as a disinfectant and air-purifier as applied by spray in school and living rooms. Great improvements had also been made with respect to certain other "Sanitas" manufactures, notably the Company's Patent Drain Testers and the two new Disinfectant Fluids known as "Sanitas-Bactox" (homogeneous) and "Sanitas-Okol" (an emulsion), both of which are now being manufactured and sold for commercial employment with a guaranteed strength at least twenty times that of pure carbolic acid, and which are available for use whenever disinfectants of high germicidal power are called for. There had been a satisfactory increase in the business of the company,. the chairman remarked, and the sales of the universally well-known "Sanitas Fluid," for sick-room and domestic applications, showed a very gratifying increase. A dividend at the rate of 7½ per cent: wasdeclared.

#### Sanitary Inspectors' Conference.

THE North-Western Centre of the Sanitary Inspectors' Association held a meeting at Southport on June: 12th. There were 120 members present from the counties of Lancashire, Cheshire, Westmoreland, and

counties of Lancashire, Cheshire, Westmoreland, and Cumberland, and a civic reception and tea were given by the Mayor. In the afternoon the members visited the Southport sewage works at Crossens.

Mr. J. T. Quinton, hon. sec., reported that the membership had increased by 41 during the year.

Mr. Allan Kendall (Southport) read a paper on "Sanitary Administration," in the course of which he said that local authorities had other things than sanitary affairs to attend to and sometimes sanitation was tary affairs to attend to, and sometimes sanitation was. neglected in favour of gas works, tramways, and other undertakings. He urged the necessity of fixing the tenure our dertakings. He urged the necessity of fixing the tenure of sanitary inspectors' appointments, and claimed that the duties of a sanitary inspector should include the supervision of new buildings. On the question of milk supply he observed that many of the owners of farms were obstacles to a pure milk supply. British farmers could learn a lesson from South American farmers could learn a lesson from South Michael farmers who attended to the healthy breeding of stock, especially on the male side. He also urged better attention to building, and the re-establishment of the services of milk maids, who were disappearing. The bacteriologist's requirements for a pure milk supply were almost beyond attainment; machine milking being the only possible means of meeting their require-

#### Royal Infirmary Edinburgh.

Two years ago the surgical out-patient department of the Edinburgh Royal Infirmary was thoroughly reorganised, and new buildings provided for it, and the medical out-patient department has been entirely re-modelled during the past year. Considerable additions and alterations of an extensive nature have been made on the part of the building in which this department was previously housed, with a view to providing better accommodation and working facilities generally for the proper carrying on of this part of the Infirmary's work. The department is situated immediately adjoining the entrance to the medical hospital, to which it is directly connected. On either side of the waiting-room are provided dressing-rooms, with lavatory accommodation for males and females. These dressing-rooms communicate by means of two parallel corridors with a large demonstration-room, with raised benches and seats, to accommodate eighty students. There are a separate entrance and staircase to the outside by which students are admitted, thus obviating the necessity for any traffic through the main portion of the department. An examination-room for females is also provided, while adjoining the demonstration-room is a private room for the physicians, and a dark room for the treatment of eye cases. A new exit has been formed, through which patients, after treatment, leave the building without having to return through the waiting-room. The whole department has been fitted up in accordance with the most approved. methods of hospital construction, and with a view to general cleanliness and convenience. A suite of rooms, consisting of a nurses' room, nurses' kitchen, and a lavatory, has also been provided, opening directly off the main vestibule. The department is warmed the main vestibule. The department is warmed throughout by steam-heated radiators, and where special ventilation is necessary an extract electrically-driven fan is provided. The walls of the various buildings are finished in polished Keene's cement, while in the waiting-room, vestibule, and corridors there is a dado of glazed tile. The floors in the waiting-room and corridors are of markle terrazzo, and ing-room and corridors are of marble terrazzo, and in the dressing-rooms and demonstration-rooms of red wood bedded in bitumen on concrete. The cost has been £3,000.

#### NOTICES TO CORRESPONDENTS. &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a Distinctive Signature or Initial, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much. confusion will be spared by attention to this rule.

#### SUBSCRIPTIONS.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January lat and July 1st respectively. Terms per annum, 21s.; post free at home cr abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Bs 15.12. Messrs. Dawson and Sons are our special agents for Canada.

Contributors are kindly requested to send their communica-

CONTRIBUTORS are kindly requested to send their communica-tions, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

B. S. (Surbiton).—We know of no rule to the contrary. On general grounds we should say the course you propose is not only absolutely safe, but perfectly straightforward and honourable. It may reasure you, however, to write explaining the circumstances to the Secretary of the Medical Defence Union, 4 Trafaigur Square, London, W.

Hospital Secretaity.—We have heard the name of the medical man you mention. His name was, if we mittake not, removed from the \*Register\* some years ago. You will never see your money again, and may congratulate yourself you did not cash the cheque as requested.

Quercus.—We will inquire into the matter, and communicate with our correspondent by letter.

Dr. Septimus.—Our correspondent will do well to bear in mind that exception probat regulam.

T. D. S.—If the offence should be repeated, notice should certainly be taken of it, either by a private remonstrance, or through the medium of a solicitor's letter.

Mr. D. B.—The bond, as it appears to be in order, should undoubtedly be enforced.

EXPERIENTIA DOCET.—A medical man who sends a patient to a consultant has obviously nothing to do with the payment of the tee of the latter. If payment is not made, either at the time, or subsequently, the consultant, after acquainting the medical man of the fact, should proceed direct to claim it from the patient, and, if necessary, through a solicitor. A patient who coluntarily incurs the expense of a consultant advice is alone responsible for the payment of it, and to him the consultant must look for the discharge of the fee.

Mr. TOM Barron.—We are unable to prescribe for the public in these columns. If you will consult your medical adviser on the matter, he will be able to help you.

### Meetings of the Societies, Tectures, &c.

WEDNESDAY, JUNE 23RD.

MEDICAL GRADDATES COLLEGE AND POLICITING (22 Chenies treet, W.C.).—4 p.m.: Mr. L. Mummery: Clinique (Surgical).

15 p.m.: Lecture: Dr. A. E. Giles: The Diagnosis of Pelvic

THERDAY, INEC 24TH.

ROYAL SOCIETY OF MEDICINE (SECTION FOR THE STUDY OF DISFASE IN CHILDREN) (20 Hanover Square, W.).—Wightman Lecture: Dr. George Carpenter: Congenital Heart Affections. ROYAL Society of Medicine (Section For The Study (20, Hanover Square, W.).—8.30 p.m.: Dr. James Collier and Dr. Gordon Holmes: Amyotonia Congenita: (1) The Pathological Findings in a Case previously shown before the Section; (2) Demonstration of a Firither Case with the results of a Biopsy. Dr. Albert Wilson: A Critical Description of the Brain of a Degenerate (a Convict and a Murdener).

ROYAL COLLEGE OF PHYSICALNS OF LONDON (Pall Mall East).—5 p.m.: Dr. W. S. Lezatus-Barlow: Radioactivity and Carchoma an Experimental Empary). (Croonian Lectures.)

Medical Graduates College and Politicinic (22 Chenies Street, W.C.).—4 p.m.: Sir Jonathan Hutchinson: Clinique (Surgical). 5.15 p.m.: Lecture: Dr. T. Hyslop: Paralysis and Insanity.

Insanity.

FRIDAT, JUNE 25TH.

WEST LONDON MEDICO-CHIEURGHEAL SOCIETY (Kensington Town Hall).—8.15 p.m.: Sir Victor Horsley: The Cerebellum. (Cavendish Lecture.)

ROTAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, W.C.)—5 p.m.: Dr. G. E. Smith: The Evolution of the Brain. (Arris and Gale Lecture.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Dr. St. Clair Thomson: Clinique (Ear, Nose, and Throat.
CENTRAL LONDON THEOAT AND EAR HOSPITAL (Gray's Inn Road, W.C.).—3.45 pm.: Lecture: Mr. Stuart-Low: Accessory

#### Appointments.

BREMRIDGE, RICHARD H., B.Sc., M.B., B.Ch.Oxon., L.B.C.P.Lond., M.R.C.S., Chief Medical Inspector of Schools for the county of Wilts.

of Wilts.

EVAMS, DAVID ROBERT POWELL, M.R.C.S., L.R.C.P.Lond., L.S.A., Medical Officer to the North Wimbledon Cottage Hospital.

Hepburn, Malcolm L., M.D., B.S.Lond., F.R.C.S.Eng., Assistant Surgeon to the Gentral London Ophthalmic Hospital.

18aAc, Charles Leonard, M.B., M.R.C.S., Medical Referre under the Workmen's Compensation Act, 1906, for County Court Circuit, No. 30.

JEFFRETS, W. M., M.R.C.S., L.R.C.P.Lond., House Surgeon at University College Hospital.

Martin, Basil W., M.B., B.Ch.Aberd., Medical Officer to the Heading Dispinsary.

Planson, J. Sidnet, M.D.Cantab., Pathologist and Registrar to the East London Hospital for Children, Shadwell.

Sweeting, R. Deane, M.D.Dub., D.P.H.Dub., Examiner for the Conjoint Diploma in Public Health of the Royal College of Physicians and Surgeons of England.

Thomas, William Myrray, L.R.C.P.Lond., M.R.C.S., Medical Officer for the No. 6 District of the Bodmin (Cornwall) Union. Vosper, S., M.R.C.S., L.R.C.P.Lond., Medical Officer to the British Lyings-in Hospital.

WILLIAMS, RICHARD THOMAS, L.R.C.P. and S.Edin., L.F.P.S.Gla-C., Medical Referree under the Workmen's Compensation Act, 1895, for County Court Circuit No. 30. EVANS, DAVID ROBERT POWELL, M.R.C.S., L.R.C.P.Lond., L.S.A.,

#### Bacancies.

Guy's Hospital Medical School (University of London).—Douglas-Research Studentship. Salary, 2300 per annum. Applica-tions to the Treasurer, at the Superintendent's Office, Guy's

tions to the Treasurer, at the Superintendent's Omce, Guy's Hospita'.

Egyptian Government—Ministry of Education.—Professor of Anatomy at the School of Medicine, Cairo Salary, £800.

Applications to "The Director, Egyptian Government School of Medicine, care of the Director, Imperial Institute, South Kensington, London, S.W."

Sheffield Union Hospital.—Resident Assistant Medical Officer. Salary, £100 per annum, with apartments, rations, and the other usual allowances. Applications to Albert Edw.d. Booker. Clerk to the Guardians, Union Offices, Sheffield.

Liverpool Parish.—Assistant Medical Officer. Salary £100 per annum, with rations. Applications to H. J. Hagger, Vestry Olerk, Parish Offices, Liverpool.

Canterbury Borough Asylum, Canterbury.—Assistant Medical Officer. Salary £140 per annum, with board, lodging, washing, and attendance. Applications to the Medical Superintendent.

Officer. Salary £140 per annum, what to be decided Superining, and attendance. Applications to the Medical Superintendent.

Manchester University.—Junior Demonstrator in Physiology. Salary £100 per annum. Applications to the Registrar. Bethlem Hospital.—Resident House Physician. Honorarium of £25 per quarter. Applications to the Treasurer, Brideaci: Hospital. New Bridge Street, £C. (See advt.)

The Hospital for Sick Children, Great Ormond Street, London. W.C.—A House Physician. Salary £30. washing allowance £2 10s., and board and residence in the Hospital. Applications to the Secretary. (See advt.)

#### Births.

HEPHTRN.—On June 14th, at Pevensey, Enfield, Middlesex, the wife of Malcolan L. Hepburn, M.D., F.R.C.S., of 66, Wimp Street, W., of a son.

SALAMAN.—On June 15th, at Homestall, Barley, Herts, the wife of Redeliffe N. Salaman, M.D., J.P., of a daughter.

WALLIS.—On June 17th, at 65 Cariton Road, Worksop, the w. sof A. Ransome Wallis, M.D., of a son.

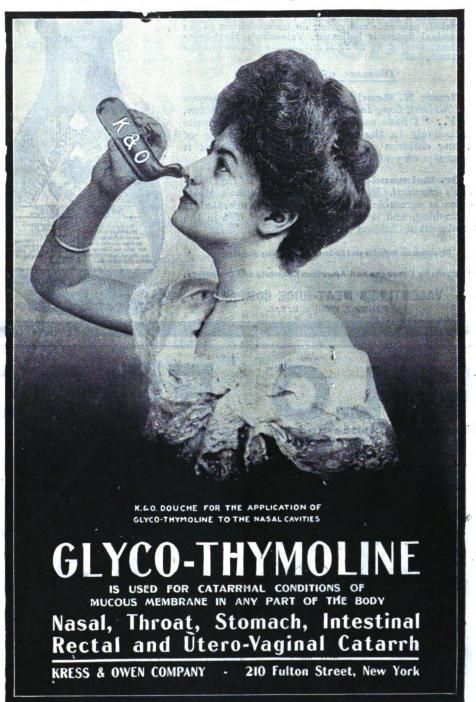

# Marriages.

ADDISCN—BROWN.—On June 18th, at St. Morylebone Parish Church, York Gate, Regent's Park, by the Rev. W. D. Morrison, Oswald Lacy Addison, F.R.C.S., of 55a Welbeck Street, London, son of Joseph Addison, of 20 Harley House Regent's Park, and Bond Court, Walbrook, London, and Kate (Cissie) Brown, M.B., B.S.Lond., daughter of Harold Brown, of 9 Chester Terrace, Regent's Park, and Bond Court, Walbrook, London.

SANDILAND—HILL—On June 19th, at St. James', West Hampstead, Digby Saver, elder son of A. H. Sandiland, LRCP., MR.C.S., and Mrs. Sandiland, of Oskley House, Cauonbury, to Lola, only daughter of Mr, and Mrs. Charles A. C. Hill, of West Hampstead.

#### Beaths.

ALEXANDER.—On June 17th, at Lyndhurst, Leigh, Essex, Samuel Alexander, L.R.C.P. and S. Edin, late of Bow, aged 53, ELLIOT.—On June 18th, suddenly, Frederick William Ethort, M.D., of 34 Bedford Square, Brighton.

Sole Agents for Great Britain, THOS. CHRISTY & CO., 4-10 & 12 Old Swan Lane, Lendon, E. C.

Examined and approved by the INSTITUTE OF HYGIENE, 34 Devonshire St., Harley St., W., where their preparation can be seen, and its properties and value can be explained.

# Valentine's Meat-Juice

Where a powerful nutrient, easily assimilated and digested, palatable and giving no inconvenience to the Intestinal Tract, is indicated, Valentine's Meat-Juice is recommended by medical authorities eminent in the treatment of

#### Diseases of Children.

Henry N. Read, M.D., Professor of Diseases of Children, Long Island College Hospital, Brooklyn, N.Y.: "I have used Valentine's Meat-Juice quite extensively in the mal-nutrition and Atrophy of young children and babies, and am confident it possesses very valuable qualities."

Dr. Raimondo Guaita, Director of the Children's Hospital, Milan, Italy: "Valentine's Meat-Juice is agreeable to the taste, is well tolerated, is nourishing, and is a valuable article of diet in the treatment of Children convalescing from disease."

Physicians are invited to send for brochures containing clinical reports.

For sale by European and American Chemists and Druggists.

VALENTINE'S MEAT-JUICE COMPANY,

RICHMOND, VIRGINIA, U. S. A.

# MILO FOOD

Isbased on Science and the Practical Experience of Thirty Years.
It is a Food with Milk as a basis.

By the simple addition of water in the proportion indicated in the instructions accompanying each tin, MILO adapts itself to children of various ages.

## MILO

is much appreciated by nursing Mothers, and is invaluable at the time of weaning.

Awarded the GOLD MEDAL at the CAPE TOWN EXHIBITION, also the CERTIFICATE OF MERIT by the Institute OF HYGIENE, LONDON.

Sample and pamphlet on "The Feeding and Care of Infants" sent free on application to

NESTLE & ANGLO - SWISS CONDENSED MILK CO., 6 & 8 Eastoheap, London, E.C.

# TABLOID 'BRAND

# HYPODERMIC PRODUCTS

'TABLOID' Hypodermic Products present the stated quantity of drug in its fullest activity and remain unaltered for many years in all climates.

They ensure accuracy of dosage and the use of reliable drugs in hypodermic medication.

They dissolve instantly, yielding solutions free from phenol, salicylic acid, or other preservative.

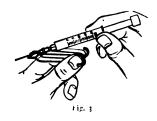

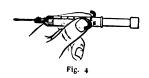

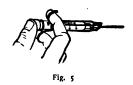

If the B. W. & Co. All-Glass Aseptic Hypodermic Syringe be employed, the required solution may be made in the barrel of the Syringe, as illustrated in Figs. 1 ana 2. Solution takes place rapidly and without danger of contamination.

Figs. 3, 4 and 5 show method of attaching and using the 'Tabloid'
Detachable Sheath-Grip

Hypodermic Medication Booklet, with full list, sent to members of the Medical Profession on request

Burroughs Wellcome & Co., London (Eng.)

# Control of Pain and Bleeding Minor Surgery.

"The great means to this end is Adrenalin."-St. Bart's Hospital Journal, Jan., 1908.

"The more one sees of this analgesia, the more it is to be preferred to general anaesthesia."—Journal Royal Army Medical Corps, April, 1905.

"I am convinced that the profession has not yet fully realised its value . . . especially in operations involving only skin-deep incisions."—Lancet, Mar. 17, 1906.

The constringent action of Adrenalin provides an almost bloodless field of operation, intensifies and prolongs the analgesic effect of cocaine, eucaine, etc., and diminishes their toxicity by retarding their diffusion, whilst its cardiac-stimulant action tends to guard against systemic ill-effects.

## "CODRENINE."

Cocaine hydrochloride (2 per cent.) and Adrena'in chloride (1 in 15,000) in physiological sodium chloride solution preserved with Chloretone.

"Codrenine" rapidly induces effective analgesia and ischæmia.

The amount of cocaine injected can be regulated to a nicety—ten minims contain one-fifth of a grain.

"Codrenine" does not deteriorate if the bottle is kept well stoppered and in a cool, dark place.

"Parke, Davis & Co. have a very convenient solution under the name of 'Codrenine.' Two friends of mine have used it extensively and are pleased with it."—Brit. Dent. Journ., Sept. 16, 1907, art. "Local Anæsthesia in Dentistry."

### "EUDRENINE."

Eucaine hydrochloride (1 per cent.) and Adrenalin chloride (1 in 30,000) in physiological sodium chloride solution preserved with Chloretone.

"Eudrenine" acts somewhat less rapidly than "Codrenine" does.

It is preferred by some, as eucaine is less toxic than cocaine and nearly its equal in analgesic power.

"Eudrenine" may be sterilised by boiling, without detriment to its analgesic properties.

"I have used for some time, and found extremely useful, a preparation made by Parke, Davis & Co. under the name of 'Eudrenine'."—Brit. Med. Journ., Oct. 21, 1905, art. "Tracheotomy under Local Anæsthesia."

ADRENALIN AND COCAINE Hypodermic Tablets, B, "A" (P., D. & Co., No. 151).

Each contains :-

Adrenalin ... ... 1-300 grain. Cocaine Hydrochloride 1-6 grain.

The solution of one tablet in 18 minims of distilled water will contain 1% of the cocaine salt.

ADRENALIN AND COCAINE Hypodermic Tablets, B, "B" (P., D. & Co., No. 181).

Each contains:

Adrenalin ... ... 1-400 grain. Cocaine Hydrochloride 3-4 grain.

The solution of one tablet in 80 minims of distilled water will contain 1% of the cocaine salt.

ADRENALIN AND EUCAINE
Hypodermic Tablets
(P., D. & Co.).

Each contains:

Adrenalin ... ... 1-2000 grain.
Eucaine Lactate ... 1-6 grain.
Sodium Chloride 3-5 grain.

The solution of one tablet in 18 minims of distilled water will contain 1% of the eucaine salt.

Prices and further particulars of these preparations, also a brochure on "Local Analgesia," which details some of the operations in which it has been successfully employed, and indicates various methods of inducing it, will be sent on request by

PARKE, DAVIS & Co., 50-54 BEAK ST., LONDON, W.

Telegraphic and Cable Aidress: "Cascara, London."

Telephones: 8636 Gerrard; 9201 Central.

# Notes and Comments.

Birthday Honours. The list of Birthday Honours announced last week is long enough to satisfy the most undistinguished of people who see in these periodical lists the only chance of marking

themselves as superior to their contemporaries. Nevertheless, as if by happy accident, among the mass of mediocre politicians and dutiful officials whose names figure in the list, there are to be found rari nantes some persons of real eminence and distinction. To these occurrences may be attributed the fact that the lists still maintain a semblance of interest outside the ranks of the Under immediately interested and their friends. our political system it is necessary to provide the Government of the day with a means of throwing sops to faithful adherents who do not embarrass them by overmuch speaking in the House of Commons, or who have helped the party cause without attaining unenviable notoriety. Our one grumble with the present Government is that they show a tendency to depreciate what should be a real distinction, namely, membership of the Privy Council, by swearing-in too many minor politicians, whilst fobbing off men who have done eminent service to the State with knighthoods and baronetcies. Huxley always held that a Privy Councillorship was the only proper recognition to be awarded by the State to scientific men, and he so far prevailed that, after refusing the Knight Commandership of the Bath several times, he was himself sworn-in of the Council. That act of Lord Salisbury's was regarded as creating a healthy precedent in the case of scientists who had achieved distinction; but, alas! it remains a solitary precedent to this day.

Wanted—
Some Privy
Some Privy
as a proper reward for scientists.
Councillors.
Both in themselves are barren
honours, and carry with them no
change in style in the ordinary address, though
the former gives members precedence at Court
before the younger sons of peers, a fact
which is not likely to lead the holders to
any giddy heights of exhilaration. We would
suggest to the Government, however, that as
the Privy Council, in theory, is the body which
guides the deliberations of His Majesty in the
regulation of the State, its ranks not only should
contain a good sprinkling of scientific and medical
men, but that such a class would add lustre to a
distinction which is now being rather rapidly
watered down by its too-frequent conferment on

persons of no outstanding intellectual attainments. We should like, too, to see the honour reserved for

men of real scientific eminence, and not given merely to physicians and surgeons who happen through some turn of the wheel of fortune to be in the public eye at the moment. We cannot imagine that even the present Privy Councillors would find much cause for discontent if their ranks were swelled by the presence of men of such worldwide fame as, for instance, Sir Clifford Allbutt, Sir William Gowers, Sir T. D. Fraser, Sir Victor Horsley, Professor Ronald Ross, Sir Thomas Oliver, and others in England, in Scotland, and in Ireland whose names will readily occur to our readers. For our part, we should be much more envious of those who are privileged to be called "Right Honourable" if those gentlemen held seats in the Council-room.

As things are at present, however, we must admit-and we do so The ungrudgingly—that the medical pro-fession is far more generously treated than of yore in the matter Present Recipients. of honours, and we fancy that one influence at work is that of the King, who has always shown himself appreciative of the work of a body of men to whom he owes so much himself. If His Majesty's happy recovery from his severe attack of typhoid fever cannot be specially attributed to medical skill—it is always difficult to prove a claim of that kind in the case of specific fevers—the excellent result which followed his fracture of the patella and the astonishing success which attended his operation for perityphlitis cannot but be largely attributed to the surgical skill which was exhibited by his attendants. These facts, we are sure, do not escape the notice and memory of a monarch who never forgets an old friend and never shows himself lacking in gratitude for services rendered. Beyond the official and military distinctions conferred last week, we have baronetcies awarded to Mr. Henry Morris and Sir Dyce Duckworth, and a knighthood to Lieut.-Colonel Leishman. In Sir Henry's case the honour is long over-due, as a baronetcy should be offered to the Presidents of the Royal College of Physicians and Surgeons in their year of office, whereas Sir Henry Morris has had to do the "hat-trick" in his post before it has come to him. We have frequently had occasion to criticise the College of Surgeons and the line taken by its representative on the General Medical Council, but we the more gladly acknowledge the leading position in the surgical profession held by Sir Henry, and we are sure that his pioneer work in renal surgery has not only won him recognition from the whole world, but will send his name down to posterity with those of Hunter and Bell. Since he received his knighthood nearly a quarter of a century ago, the name of Sir Dyce Duckworth has been almost a household word, and his recognition abroad as one of the representatives of British clinical medicine makes his present distinction all the more appropriate. Colonel Leishman's knighthood is particularly pleasing in view of the fact that it is due wholly and solely to his scientific work—and of what immense value that work is, scientists in every Continent know. Of the many brilliant men in the band of researchers in tropical bacteriology and pathology, none is more brilliant than the new knight. To all three gentlemen we offer our hearty congratulations.

Sacco's Latest Fast. In the Hanley County Court, last week, Dr. W. T. Brand brought an action against two men who acted as agents for Sacco during a fast lately undertaken by that celebrity,

to recover five guineas, the balance of a bill for medical attendance on Sacco during the fast. We have always been a little suspicious of these advertised fasts, but in evidence Dr. Brand stated that he himself was responsible for the bulletins and for the number of bottles of soda-water drunk and cigarettes smoked by Sacco. We therefore are led to conclude that Dr. Brand is responsible also for the genuineness of the performance, and we shall in future have a more comfortable feeling when we read of these fasts, if relieved of the sensation that there is no hanky-panky about them. genuineness is further confirmed by the fact that Sacco was very ill during the last few days of his confinement, which is not indeed surprising if he had had no food for nearly six weeks. The wonder is that he lived to complete his self-imposed task. The report before us is not very clear as to what was the substance of the defence put forward, but we rather gather that the medical attendance was denied, or cut down, because Dr. Brand could not do anything to Sacco because he was shut up in a glass case for his performance! We can imagine that it is difficult to treat a case through such a barrier, but clearly, if a medical man is sent for to attend a patient and to take the responsibility as to his condition, his work is not lessened-rather greatly increased—by having no means of access to him. The judge, we are glad to say, took the same common-sense view and gave judgment for Dr. Brand's claim.

#### LEADING ARTICLES.

# THE CONTROL OF UNQUALIFIED PRACTICE.

The success that has followed the efforts of the British Dental Association to put a stop to irregular dental practice may well encourage the medical profession to fresh endeavours in a similar direction. As the result of a series of successful prosecutions, the unqualified person who even remotely implies that he is entitled to practise dentistry is liable to condign penalties. In a word, the quack dentist, to use a homely phrase, is dead as a door nail. As we all know, it is only within comparatively recent years that the Dental Acts were passed legalising the profession, rendering proper qualification obligatory, and imposing penalties upon a practice. On the other

hand, the medical profession has possessed penal powers of a stringent nature ever since the days of King Henry VIII. In spite of those powers, which have been confirmed, strengthened and extended by subsequent Acts down to the Medical Act of 1858, quack medical practice of every kind is still rampant throughout the length and breadth of the United Kingdom, and the penal provisions of the Medical Acts are so readily evaded, that "false practitioners," as they were called in King Henry's day, simply snap their fingers at the law. The section of the Medical Act intended to restrain these rogues has been interpreted so that nowadays any unqualified person may practice medicine without let or hindrance, provided he does not call himself "doctor." Were this section to be applied by magistrates with anything approaching the rigorous way in which they have maintained the corresponding principle in the Dental Act, the days of the medical quack would be speedily numbered. Why the dental pirate should be ruthlessly exterminated while the far more dangerous pseudomedical brigand is allowed to carry on his nefarious pillage unchecked is a profound mystery. power to do harm is in the one case limited almost entirely to the mutilation of teeth and jaws, while in the other instance it may, and often does, inflict an incalculable amount of damage upon the health and life of the community. The failure of four hundred years of legislation to remove so great an injury to the public weal is remarkable in various ways. The fault certainly does not lie in the laws themselves, for however loosely-worded in places, they nevertheless, by expressly confirming the powers of King Henry's Act, reiterate again and again the principle that the people must be protected against false medical practice. To some extent the blame may rest upon too lenient an interpretation and administration of statutory powers. Yet in the long run it may be doubted whether the medical profession is not mainly responsible for the growth and the continuance of this unclean thing. By the creation of duly qualified medical practitioners a monopoly in conferring qualification was conferred upon a certain body of men in London, and it was expressly enacted that they were in turn to exercise special control over quacks and quackery. The privileges have been retained, but the duties have been permitted to lapse, and, later, were imposed upon the General Medical Council only so far as the discipline of qualified practitioners was concerned. But what have the qualifying bodies, the colleges, the universities and the halls done to protect their alumni and the public against false medical practice, and what are they doing at the present moment in return for the enormously valuable privileges conferred upon them by the legislature? That question may be answered by the brief statement, that in the past they have done nothing, or next to nothing, and at the present moment are doing nothing whatever by way of recompense to the State from whom they have received their privileges, or to the medical men from whom they have received their pelf. Can any single instance be quoted in which any college, university or other medical qualifying body has petitioned the State with a view to the suppression of unqualified practice? Has the General Medical

Council ever brought its enormous influence to bear upon the Privy Council in a similar direction? The latter body has attempted to justify itself by a plea of non possumus, but had the Council been elective and really representative of the medical profession, we venture to say that it would long ago have obtained from Parliament the necessary powers for the protection of the public and of medical men against false or unqualified practice. Why should not the colleges and universities petition the Council and the State for the conferring or the re-enacting and strengthening of penal powers that are urgently needed in the best interests of the community? The root of the evil may undoubtedly to a great extent be found in the fact that all, or nearly all, the qualifying bodies are close corporations governed by a small knot of privileged men, to whom the chartered body is everything and the diplomate or graduate nothing. In the reforms that one day must overtake the medical profession, a prominent place must assuredly be given to the transference of government to constituent graduates and diplomates of all degrees. We have long advocated a Royal Commission upon quacks and quackery, but a necessary corollary will be an inquiry into the way in which the qualifying bodies have discharged their statutory obligations in the control of these offences. Some way out of the present intolerable state of affairs with regard to unqualified medical practice must be found, and we cannot avoid the conclusion that medical men would find the strongest and best friend in their own right hand, if only they took up the matter with wholehearted and collective enthusiasm.

#### CURRENT TOPICS.

# Sickness Insurance and the Medical Profession.

We recently took occasion to warn Mr. Lloyd George that if he institutes the system of compulsory sickness insurance, which he hopes to bring forward next year, without due consultation with the medical profession, he is almost certain to create a situation which will be unworkable. We know that the Chancellor of the Exchequer has been making inquiries in many directions, and we believe from what has been announced that the system will be an excellent one in theory. It is all the more imperative that it shall not break down in practice. Such a scheme will touch the profession at many points, and it is necessary that its details shall be discussed with accredited representatives of the medical profession if it is to be just and successful. Mr. Lloyd George has shown himself so accessible to bodies interested in his other schemes, both when he was at the Board of Trade and since he was raised to his present important office, that we believe the matter has only to be brought to his notice for him to realise the necessity of it. Naturally, the Government wish to make their system as cheap as possible, but that desideratum may easily lead to a loss of efficiency, if not complete breakdown. In Germany a new scheme of insurance for the working-class is being introduced under which medical men will have to give their services almost gratuitously, and the doctors are organising a movement to refuse to attend insured patients if the proposals become law. We are not in possession of sufficient detail to be able to express an opinion on the justice or advisability of this course, but we do know from precedents at home and abroad that it is usual to look upon the doctor as the willing beast of burden for all Government schemes that cost money. It is far better that the profession should be consulted before Mr. Lloyd George's proposals see light than that they should find it necessary to oppose them when they are brought forward, and we beg the Chancellor of the Exchequer and his advisers to take heed in time.

#### Two Epidemics.

An odd and interesting occurrence is reported from Saddleworth, namely, the co-existence at the moment of two epidemics. One of these is the harmless, necessary mumps, the other a much rarer one, namely, an outbreak of erythema nodosum. In the absence of precise details as to the number of persons affected and the distribution of the diseases, it is not possible to form any intelligible theory as to the origin of the two outbreaks, or as to whether there is any connection between them. The medical officer of health has said that there is no connection between the occurrence and any of the local industries, and it is also remarkable that none of the adjacent districts are affected. epidemic of mumps has become so widespread already that one school has had to be closed, but otherwise the disease does not appear to exhibit any but ordinary features. That erythema nodosum, however, should occur in epidemic form is very uncommon, though not quite unprecedented. The symptoms which are said to be found in the present patients are sore throat, little if any fever, general pains, and the characteristic eruption of the legs and forearms. Some cases are complicated by pericarditis, tonsillitis, pleurisy and acute anæmia. The chief prophylactic measure advised by the sanitary authority is the gargling of the throat and mouth with disinfectants. Doubtless in time we shall have a report on the subject, and we hope that it may be possible to trace the outbreak to its source—a matter which should not be so difficult in the case of erythema nodosum as in that of the common infectious diseases, which, owing to their widespread prevalence and easy distribution, frequently baffle the most lynx-eyed of medical detectives.

#### Vicious Children.

We have never been able to make up our minds definitely as to Dr. Rentoul's scheme for the sterilisation of degenerates. Theoretically, it is monstrous that inveterate criminals and lunatics should be allowed to propagate and reproduce in their young those anti-social qualities which have made their own lives a curse and entailed much misery and expense to the community. On the other hand, it is optimistic in the extreme to think that society will accept the rational method of prevent-

ing reproduction which Dr. Rentoul proposes. If any additional argument were needed for the necessity of action of some kind it is to be found in Dr. Kerr's Report to the Education Committee of the London County Council. Leaving aside the physical defects, we may turn to some examples of moral degradation which he sets forth. There are recounted tales of children of ungovernable temper, destructive outbursts, and murderous tendencies. "Manslaughter has been committed by children of innocent, pleasant, and in one case of angelic appearance." The cherub in question was so far oblivious of moral obligations as to try to drown another child; another little terror flung the baby across the room, and a third "probably" drowned a companion. One child of nine killed a cat with his hands and it required four people to take him to school, whilst another of like kidney and the same age set fire to his parents' house. Nearly all the children in this class were relatives of drunkards. imbeciles or lunatics, and Dr. Kerr opines that these morally defective youngsters require to be taught by regular and inflexible corporal punishment. No doubt the rod should frequently be taken out of pickle for these wretched children's benefit, and often has a salutary effect in the milder cases, but many have no future as men and women but that taken by their degenerate relatives, and it is grave, perhaps the gravest, moral question as to whether they should ever have been allowed to be born.

The Daylight Saving Bill.

AMONG recent witnesses before the Parliamentary Committee on the Daylight Saving Bill was Sir Thomas Barlow, who, speaking, according to the newspapers, from the medical point of view, gave his blessing to the Bill. The most natural mode of living would be to use as much of the hours of sunlight as possible, leaving the hours of darkness for rest. The limiting of working hours to the hours of daylight would, by doing away with the use of artificial light, do much to safeguard the eyesight of workers. In these pronouncements, of course, every sensible man, whether lay or medical, will agree. We would very much like to see a general agreement to make our active diurnal period coincide more closely with the hours of daylight, but we do not think that the habits of a nation are to be changed by tampering with clocks. The proposal in the Bill, indeed, seems to us so impracticable, that we have been surprised to see that quite a number of otherwise level-headed people are supporting it. It should not go forth, however, that because Sir Thomas Barlow favours the Bill, authoritative medical opinion is with him and endorses the method proposed.

#### Identification by Veins.

A NEW suggestion of some interest and importance in the science of criminology has been made by Dr. Tomassia with regard to identification. Briefly summarised, his plan is that identification can be better established by the disposition of the veins of the back of the hand than by any other method, and his suggestion is that a bandage

having been tied tightly round the wrist in order to render the veins prominent, a photograph should be taken of the back of the hand. The present system, of course, is identification by means of finger-prints, a system invented by Colonel Henry. elaborated by Professor Galton, and generally The chief argument ascribed to M. Bertillon. advanced by Dr. Tomassia is that it is almost impossible for a criminal of whose veins the police have a record to destroy the marks of identification by artificial means. It is said that at present criminals whose finger-prints are recorded can mystify the police by defacing their fingertips either by cutting the pads of the fingers with knives, or of burning off the epidermis and thus creating new lines. We doubt if either of thus creating new lines. these practices is really established, but, at the same time, there can be no harm in adopting Dr. Tomassia's plan as corroborative evidence if it is sufficiently systematised to render trustworthy evidence. That it can supersede identification by finger-marks as a general system we do not believe for a moment, for, apart from the specific value-already generally admitted-of the disposition of the whorls, so sure is the finger-print system that over and over again criminals have been identified and brought to justice solely by means of impressions of the pads of their fingers left on doors, glasses and other objects in the room where the crime has been committed. However specific the venous system of identification is, it could never give this evidence, though as corroborative evidence we can conceive of its being of great importance.

#### Inebriate Reformatories.

THERE is no question but that Mr. Ritchie's plan of inebriate reformatories has in practice broken down. We do not say that as any reproach to a Home Secretary who, by his gifts and influence, was able to initiate a system strongly opposed by that large section of the community which holds that a man (or woman) has a right to get drunk as often as he likes, if he does not cause a nuisance to hisneighbours. Rather should we use this breakdown as an argument for still further extension of the system and for granting still further powers to those in charge of reformatories. Magistrates are doubtless, as a class, high-minded gentlemen, but their idea of drunkenness is mainly confined to the imposition of a five-shilling fine, with or without option. Of the disease, inebriety, they know as little as they do of dementia præcox or general paralysis of the insane. Their training gives them as little insight into pathological problems as it does into the intricacies of building an aeroplane. The one cardinal factor which stands out at the moment is that the control of reformatories and the detention of inmates should be under the supervision of expert medical men, in exactly the same way as the control of lunatic asylums is at present. From north, south, east and west we hear that reformatories are expensive and do littleer no good. We reply, What good would lunatic asylums, fever hospitals, or other essentially medical. institutions do if their inmates were sent by magistrates' orders for a period of definite detention, irrespective of their malady or the treatment needed? We trust the Government will find an early opportunity of pushing forward legislation on the lines recommended by the Royal Commission on the Feeble-minded and the Departmental Committee on Inebriety.

The Preservation of Dead Bodies.

For various medico-legal purposes it is clearly of advantage to have at disposal some simple, yet efficient, means of preserving dead bodies. So far as medical men are concerned, a process of the kind would rob the post-mortem room of much of its unpleasantness, and, in all probability, of not a little of its attendant risks. Then, again, in the case of coroners' juries and of persons called upon to view bodies for purposes of identification, the use of a refrigerating or preservative apparatus constitutes an unspeakable boon. Our attention has been drawn to an excellent apparatus which has been established in the City of London mortuary. It is made on the système de Richter plan, widely adopted on the Continent, and obtainable from the English agents, Messrs. T. Christy and Co., Swan Lane, London, E.C. The body is placed on a metal litter in a large rectangular box, furnished with windows of glass through which the body can be seen. The box is filled with an evaporation chamber containing cloths kept constantly moist with formaldehyde. By means of a small electric motor the vapour from the antiseptic drug is kept circulating round the body, with the consequence that the processes of putrefaction are quickly and completely arrested. The many advantages of this method are so obvious that there is no need to detail them to our readers. The chief wonder is that something of the kind has not been long ago introduced into all mortuaries in which large numbers of bodies are habitually lodged.

#### Burial of the Dublin Poor.

DURING the past few weeks there has been much discussion in Dublin with regard to the management of the large cemeteries adjacent to the city. It is alleged that the fees charged for the purchase of plots and opening of graves are extortionate, and though the charges for the burial of the poor are not complained of, yet it is alleged that the circumstances under which such burials take place are such as to constitute a scandal, if not, indeed, a danger to the public health. At a meeting of the Corporation, at which the matter was discussed, one of the speakers stated that in the part of Glasnevin Cemetery reserved for the poor, there existed a large pit in which the coffins were placed side by side and in tiers until the pit was full. It was stated that coffins might thus lie unburied for days or weeks, and that at times a very unpleasant odour was observed. If the condition of affairs is as described, we can hardly believe that the sanitary authorities would not ere now have intervened. A rather unfortunate result of the discussion is that the entirely irrelevant subject of the provision of bodies for dissection has been dragged in. At the Dublin Boards of Guardians debates are pending as to the conditions under which the

guardians will permit bodies of inmates to go to the medical schools for dissection. On many occasions, when ultra-sentimental guardians have endeavoured to place difficulties in the way of medical education, the Boards have shown their common-sense by declining to listen, and we hope they may continue the same enlightened policy.

#### PERSONAL.

On the 24th inst., the King and Queen attended the dedication services of the Memorial Chapel at the Queen Alexandra Military Hospital, Millbank.

It is anticipated that the King, who goes to Manchester on July 6th to open the new Infirmary buildings, will also visit the University in that city.

Dr. G. RICHELOT will preside over the twenty-second Congress of the French Surgical Association, to be held in Paris in October.

Dr. Septimus Barnett presided at the fifty-fourth annual dinner of the West Kent Medico-Chirurgical Society on June 18th.

Dr. W. T. CLAY, of Holyhead, has been placed by the Lord Chancellor on the Commission of the Peace for the County of Anglesea.

PROFESSOR LANDOUZY, Dean of the Faculty of Medicine of Paris, will preside at the annual meeting of the French Association for the Advancement of Science, to be held at Lille in the first week in August.

MAJOR J. ROBERTSON REID, M.D., R.A.M.C. (T.), has been selected as an Honorary Associate of the Order of St. John of Jerusalem in England, in recognition of his good work in connection with ambulances.

AMONG the recipients of Birthday Honours are Mr. Henry Morris, thrice President of the Royal College of Surgeons, England, and Sir Dyce Duckworth, Consulting Physican to St. Bartholomew's Hospital, both of whom receive baronetcies.

Another recognition of good work which will be popular to the profession is the conferment of the dignity of a Knight-Bachelor on Lieutenant-Colonel Leishman, Professor of Pathology at the Royal Army Medical College, Millbank.

In addition to the names already mentioned for the Chair of Surgery of Aberdeen University, it is understood that a further candidate is Dr. D. M. Greig, Dundee, Lecturer on Clinical Surgery in St. Andrews University.

At Leuchars, on June 19th, Dr. John Constable, who is retiring from practice, after the long period of 46 years, was presented by a few private friends with a handsome silver salver and a large purse of sovereigns.

MR. SIMEON SNELL, F.R.C.S., of Moor Lodge, Sheffield, Professor of Ophthalmic Surgery at University College, Sheffield, who died on April 17th, aged 57, left estate of the gross value of £30,451, with net personalty £26,883.

SURGEON-GENERAL EVATT, C.B., will preside at the annual dinner of the Poor-law Medical Officers' Association at the Waldorf Hotel on July 6th. The Honorary Secretary of the Association is Dr. Major Greenwood. The Lord Mayor and Lady Mayoress have invited members and their wives to tea at the Mansion House in the afternoon.

### A CLINICAL LECTURE

ON THE

#### CLINICAL EXAMINATION OF SPINAL CASES. (a)

By J. JACKSON CLARKE, M.B. Lond., F.R.C.S.,

Senior Surgeon to the Hampstead and N.W. London Hospital, and Surgeon to the Royal National Orthopædic Hospital.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

LADIES AND GENTLEMEN,—I have chosen for to-day's conversation a subject which has been regularly before me during the last 14 years, that is to say, the clinical examination of spinal cases.

Our first mental act when confronted with a spinal affection is to recall the natural form and mobility of the spine. We know that in the fully flexed position the human spine makes an unbroken C-shaped curve. In the extended position it also makes a C-shaped curve, but not quite such a smooth one, because the extension movement in the cervical and lumbar regions is greater than it is in the dorsal region. The lateral flexibility of the rotation movements must also be kept in mind. When we first see a patient with the view of ascertaining the condition of the spine, we must always be on the look-out for any péculiarity of attitude which the patient assumes, especially when he is not aware that we are watching him. I need only mention the stiff neck of a child with cervical disease, who often supports the head with the hands, that the elbows resting on the chest; or the manner in which a patient with lumbar disease picks up any object from the floor. For inspection of the spine, when the patients are not too ill to sit up, I prefer to have them on a firm level stool in front of a window, preferably one looking northward, with good diffuse daylight, the feet comfortably resting on the floor or on a firm footstool.

Let us take congenital abnormalities first. All the different forms of spina bifida are congenital malformations of the spinal column, and even the slight degree known as spina bifida occulta, when examined by the Röntgen rays, will often be found to be associated with a large defect of bone in the sacral region. Another congenital deformity of the spine is Sprengel's deformity, or congenital elevation of the shoulder. I show you the skiagram of a patient who came to me some years ago, and had been treated by being kept on her back for two or three years, on the supposition that she had lateral curvature. Her lateral curvature was born with her, and could never have been any different. The scapular muscles are also affected in these cases. In another case I had, the diagnosis was made by the schoolmaster. He diagnosis was made by the schoolmaster. He told the class to hold up their hands, and this boy could not get his above the shoulder, and he had a caning for obstinacy; and that led to the condition being recognised. Notice how much the spine is deviated laterally, and the curious deformities there are in the ribs in this condition of congenital elevation of the shoulder. I saw that young lady ten years ago for the first time, and told her there was nothing to be done except to make the best of things. She has not got any worse since then.

Another congenital affection of the spine, which I

Another congenital affection of the spine, which I have illustrated here, is a slight degree of that which, when severe leads to the formation of an anencephalus. I have no doubt this, like so many congenital deformities, is caused by a deficiency of liquor annii at a certain period of development. In such a fœtus the head is pressed down on the chest; there is no brain, and the spinal canal is open from skull to sacrum. In a lesser degree the head is bound down rigidly on to the chest; I show two examples of the condition. Here the brain and spinal cord

Let us pass now to cases where there is a history of some traumatism. When we are told a person has had a fall and ricked the neck, we always have to very seriously consider the possibilities. It is not uncom-nion in connection with head injuries to hear of a patient going to hospital and being sent home with a few stitches in his scalp, and being found dead in bed next morning. That is not so common in spinal injury, next morning. That is not so common in spinal injury, but it happens now and again that a person who has had what he looks on as a slight "crick" has really suffered diastasis, that is, a momentary dislocation or fracture, which has righted itself, but on some fresh sudden movement it may return, and this time with pressure on the spine, with possibly fatal results. So here the importance of X-rays in the diagnosis of spinel conditions comes in Have in the diagnosis of spinal conditions comes in. Have the patient very carefully moved, and see whether there is a temporary fracture or dislocation, or a mix-ture of the two. Another class of traumatic spinal cases are those of spinal neurasthenia. Amongst these are included cases of "railway spine": and both have as their special symptom, spinal irritation. I have as their special symptom, spinal irritation. I have seen strong men who have had an accident, and suffered from spinal irritation for months afterwards. We see it also in women whose nervous systems have been overtaxed. This spinal irritation and hyperæsthesia of the skin on each side of the spine is often so great that the least touch with the fingers is agony, and the slight pressure touch with the fingers is agony, and the slight pressure of the clothes is too great. In such cases some relief is afforded by applying an instrument which presses firmly where it does touch, and yet keep the patient's clothes away from the body. The causation of spinal irritability in spinal neurasthenia I am a little uncertain of, because it is not limted to the neurotc type of case. I have seen it, but only in rare cases, in severe tubercular disease of the spinal column of children, otherwise free from any nervous symptoms; in one such case it was very marked and only very gradually disappeared in the course of years during the progress of the case. Thus we cannot dismiss this symptom of spinal neurasthenia as being always unassociated with organic changes.

That brings me to another type of case, in which there is considerable irritability in the spine, tender

That brings me to another type of case, in which there is considerable irritability in the spine, tender spots, pain in the back, generally about the middle, associated with patches of anæsthesia in the feet or legs. Some might be inclined to include those among cases of spinal anæsthesia, but I regard them as toxic.

are not affected. One feels that there is a defect of vertebral arches, and both these patients a lady, at. about 20, and a boy, at. 4—were singularly intelligent people. The lady was too far grown up for operative treatment; but in the boy, by dividing the sternomastoid muscles, I was able to make him a neck, as shown in this picture. Those conditions are worth studying, because that operation has made a great difference in the boy's position in his family; he can now look straight before him, instead of appearing to be perpetually searching the ground. I believe this was the first time that condition had been so treated. In him I examined to feel the condition of the sternomastoids before operation, but the head was so much down on the chest, that until I had made incisions I could not tell whether the sterno-mastoids were present or not. So the clinical examination in that case was completed under an anæsthetic and through an incision.

<sup>&#</sup>x27; (a) Delivered at the Polyolinic Chemies Street, W.C., on Thursday, June 19th, 1909.

They are generally associated with long-standing constipation; and a three or four weeks' course of regular clearing-out of the bowels by enemata and aperients such as cascara, combined with massage of the spine, will clear up the whole condition permanently. From such a history that of spinal neurasthenia is different, as a rule, for when we succeed in getting a good result in this latter it has usually been a matter of months, not weeks. I consider it a toxic condition, leading to certain spinal nerve root vascular changes.

I would also mention hysterical affections of the spine, and those we see among people with exhausted nerves. The worst case I saw was in a woman who for many years suffered from lichen planus, which is a very torturing affection, and often difficult to make any impression upon. The marked lateral curvature in that case I found it very difficult to affect. In some cases good feeding and wholesome surroundings will put matters right.

When examining a patient, we have to keep our anatomy, physiology, and pathology clearly before us. Disease, of course, means some pathological process, and therefore I shall deal with the remaining condi-

tions under pathological headings.

Take a group of inflammatory spinal cases: acute infective osteomyelitis, that form of pyæmia which affects the bones, occurs in the spine sometimes, but I have seen only one case of it out of many thousands of spinal cases. Still, it must be borne in mind. The general and local symptoms are severe pain. If it is in the cervical region or the lumbar region we may find pus in the usual places, in front of the spine. If it is in the dorsal region, pus is not so readily found on exploration, but by the simple method I have on exploration, but by the simple method I nave employed, of just taking out the tip of the transverse process and part of a rib, even in the dorsal region, we may easily find if pus is present on the sides of the bodies of the vertebræ. In some cases I have seen, tuberculosis has been so rapid that I was in doubt whether or not it was acute infective osteomyelitis, the tip to can whether a characterise and acute the second s that is to say, whether a streptococcus or staphylococcus was at work, and not the tubercle bacillus. But on putting the patient to bed and treating her, the condition slowed down, and proved to be tuberculous.

Acute rheumatism sometimes affects the spine, but not often; so do gonorrheal pyæmia and other acute infections. The symptomatic pain in the back of fevers such as small-pox are to be remembered; here local examination would fail to reveal anything; and a doctor who is on the look-out for exanthems will soon recognise what may be going to happen, and watch for an eruption.

Next chronic inflammatory affections and new growths. Many of these are familiar: tubercle, rickets, osteoarthritis, typhoid, and chronic gonor-rhœal lesions, actinomycosis, sarcoma, carcinoma, hydatids. I shall deal with a few of these in detail.

Some years ago there was described in Continental literature a condition called Rhisomelic Spondylosis, meaning a chronic inflammatory affection of the spinal column with the root joints, that is to say, shoulders and hips. It is generally recognised that this is only one variation of rheumatoid arthritis, and it is such a rare condition that I have seen only one instance of it in 14 years.

Now comes a large group of cases of antero-pos-terior and lateral deviations of the spine, lateral cur-vature or scoliosis included. The ordinary round shoulders of the weakly modern, of any age whether from adenoids, or novel-reading, or whatever type it may be—is only too familiar to us. It is also known as excurvation of the spine. Dorsal kyphosis is the more scientific appellation. It is very often associated with undue hollowness in the lumbar region that is to say, dorsal kyphosis and lumbar lordosis often go together, and they are frequently combined with scoliosis.

Lateral Curvature.—When we recognise lateral curvature of the spine in a patient, it is not sufficient to diagnose scoliosis; we must give an anatomical and pathological diagnosis, and an idea of the stage of the affection. Take an ordinary type; convexity to the right in the dorsal, to the left in the lumbar region:

this we speak of as right dorsal-, left lumbar-convex scoliosis: or instead of there being two or more curves scoiosis: or instead or there being two or more curves there may be a single one, and then it should be described as a total left- or right-convex scoliosis, as the case may be. Then the pathological diagnosis. Many of these cases are simply the result of general weakness from a lack of fresh air and outdoor exercise and unhabits, babits, and most of them are associated with healthy habits, and most of them are associated with some pathology, if it is only anæmia; many of them with a definite pathology of rickets, many from an inherited a definite pathology of fickets, many from an innersted tendency to arthritic deviations from normal nutrition, which we need not particularise beyond that. They tend to be irritable in temper, and sometimes show it during examination; they have an excess of urates in their excreta, and so forth. You may require to very carefully ascertain what is the best form of courselment for them, and give planty of it. While nourishment for them, and give plenty of it. While speaking of scoliosis I would say you must be very careful not to make mistakes. I had one poor girl brought to me three years ago for a lumbar scoliosis, low down. There was something unusual about the appearance of it, some thickening of the tissues over the outer part of the ileum. A skiagraph helped us, and showed a large sarcoma, involving the bones. Previously the diagnosis had been merely scoliosis. Another case, which I described some years ago, I have seen for the last ten years. She had been treated for scoliosis, and held one shoulder very high. But examination showed it to be quite fixed. On feeling round the borders of it I found there was some thickening under it. Incision under an anæsthetic showed it to be a thick white growth adherent to the ventral surface of the scapula, under the ribs. Microscopical examination showed a very dense fibroma, such as are met with at the base of the skull, and lead to a frog-faced appearance. We removed as much as we could. It went into the thorax, and could not all be got away. For months it spread slowly up alongside the neck, causing. by pressure on nerve roots, great pain. Aspirin came into use about then, and I tried it. It stopped the pain as long as the patient took it, but the pain returned when she did not take it. The growth began to diminish in size, and finally disappeared. It left her with a stiff scapula, but there is no more growth or pain. I have watched her for several years, and it is still well. It is possible that this fibroma has been cured by the aspirin.

Another condition mistaken for scoliosis I also described at the Clinical Society. It was a contracted rectus abdominis, which had pulled the child round on one side, causing definite lumbar kyphosis and scoliosis. By dividing the rectus muscle that scoliosis was cured. So there again it was not an affection of the spinal column, but a deviation depending on one solitary muscle. Many cases of wry-neck are mistaken for scoliosis; they do cause scoliosis, but that is only a secondary condition-what may be called symptomatic scoliosis.

We must notice whether lateral deviation is masked by rotation. To do that we make the patient bend down, and then we look horizontally along the back. In a patient whose furrow is straight, we may see one part of the posterior thorax is higher than the other. That means that the lateral deviation has been masked by rotation. This rotation is nearly always towards the side of the convexity, and therefor it turns the spine in towards the concavity of the curve. Thus in the slighter cases of scoliosis the spine is straight, looked at from behind. But we must be on the look-out for scoliosis paradoxa, where the rotation is in the opposite direction.

In addition to the pathological causes of scoliosis which I have mentioned, there is cretinism which is being treated by thyroid extract. causes such improvement in nutrition that the patient shoots up like a forced plant, and the bones are not strong enough to bear the new weight, and begin to assume spiral forms. Deviation of the spine in such a case might, perhaps, be prevented by suitable treatment, including rest in bed.

There is a class of nerve diseases which cause scoliosis, and we must bear them in mind when we have what we take to be a case of simple scoliosis.

Tuberculosis is so familiar that I shall not say much

about it. X-rays are helpful in recognising it. Here about it. X-rays are helpful in recognising it. Here is one which shows marked destruction at the root of the neck and another in which a tubercular abscess was causing paraplegia. This other skiagram is very interesting to me, because there is not only a disc of darkness, but a darkness ensheathing the spine, showing tuberculosis spreading along the spine in the periosteum and ligaments. That was a paraplegia in which I trephined many years ago, and the lady is quite well at the present time. In these tubercular cases we look out for rigidity; but in early cases the rigidity is not complete, and we can often make a child with early tubercle bend down somewhat, when we shall notice a little break in the smoothness of the we shall notice a little break in the smoothness of the curve. In the rickety spine the bend takes place at the upper part of the lumbar region. These rickety cases are often very difficult to distinguish from the tubercular, and when in doubt we have to treat them as if for tuberculosis. Luckily, it is good for both; rest is good for a rickety spine, and it is necessary for a tubercular spine. Girdle pain, etc., must be looked for, and the sign of early psoas abscess, namely, a slight bending at the hip-joint.

In adults there is no more important nerve sign that I know than Babinski's reflex: stroking the sole of the foot and getting a marked extension of the great toe. That is a very important sign of organic disease of the spinal cord. We get it in early cases of compression paraplegia from spinal disease. Spasticity of muscles, ankle clonus, etc., are expressions of slight degrees of the same compression which causes complete paresis

when it is more pronounced.

Next I would say a word about syringomyelia, which causes scoliosis. Yesterday I had a patient, a big girl, who, two years ago, became scoliotic. There is great weakness in the muscles of the hands, weakness especially in the legs, and also lateral curvature. On putting her on the couch and stroking each foot down, there was a tremendous Babinski reflex, so at once one said it was not an ordinary case of scoliosis; there is something organically wrong with the spinal cord. The history was that just before the onset of her lateral curvature she had what her mother called rheumatism in the neck, and her head was drawn back for many weeks. She has had posterior meningitis, and the foramen of Magendie was blocked by that, and there has followed dilatation of the central canal of the spinal cord, causing syringomyelia. Recently Dr. Sutherland asked me to see with him a case in order to decide whether we were dealing with tubercular spine, with pressure on the spinal column, or whether it was disseminated sclerosis. The man had a very marked spastic condition, and some little nystagmus and tremor in the hands, but no marked change in the speech. I could not tell until I had an X-ray picture taken, and then it was seen to be very like the picture I have shown you, with a shadow extending along the spinal column.

The next condition I would refer to is pain in the back, localised at one rib. I described this also at the Clinical Society some years ago, and last year, at the meeting of the British Medical Association a Belgian professor described it again as a new thing. It projection of the end of the 12th rib, Ît is a painful indeed, due to inflammation of joint, between the 12th rib and the vertebra. the removed the projecting outer portion of that rib, and removed the projecting outer portion of that he, and there has been no more trouble. The weakening of the ligament by the inflammation of the joint, and the pull of the muscles, caused that rib to project, and when the projecting portion was removed, there was no lever for the dress to work on and cause irritation of the joint. We have to be careful not to mistake osteo-arthritis of the spine to be careful not to mistake osteo-artifities of the spine itself or of that joint for ovarian pain, or any other pains in the back. One patient I have in hospital now had a combination of movable kidneys and osteo-arthritis of the spine. I gave her the benefit of the doubt to see whether osteo-arthritis of the spine accounted for her pain and other symptoms. I gave her a good rest in hed, but her troubles got worse: her a good rest in bed, but her troubles got worse; she began to vomit very much. So I had her in hospital, and fixed both her kidneys by double nephrorraphy. I saw one painful case, in which both ovaries

had been removed for pain in the back. It was due to rheumatoid arthritis, which, of course, was unin-

fluenced by the operation.

One last case I would bring to your notice: of a young woman who has a very pronounced lordosis. She could neither sit in comfort nor stand, and in lying down she had a sort of Marble Arch under her back, which was filled up with pillows. For some years I lost sight of her. Since then she has been to years 1 10st sight of net. Since that the benefit of some very skilled examinations, which excluded nervous disease. concluded that it was a primary lordosis, due to shrinkage of the erector spine muscles. When we attempted to straighten her back, the muscles became very tight on each side of the spine. So I prepared myself for an ample operation of elongating these muscles, but I thought I would first try simple subcutaneous section, and put a narrow scalpel in and divide the whole erector spinæ muscle. I was surprised to find there was no bleeding. It diminished her lordosis by half, and at a later operation I divided the same muscles a little higher, and the infraspinous ligaments, and her lordosis is almost gone now, as the patient lies in bed. This observation illustrates the value of continuous study of spines for a good number of years. When I first saw her I had not realised the fact that this patient's spine might be compared to a foot in a case of simple pes cavus, where there is no paralysis to account for it; but the fascia and the muscles have either not developed, or have shrunk, and I thought I would treat that lordosis in the same simple fashion as we treat pes cavus, and so far this line of treatment has succeeded as well as, or even better than, I expected. How far the improved form will be maintained remains to be seen.

Note.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Clinton T. Dent, F.R.C.S., Surgeon to St. George's Hospital, and to the Metropolitan Police Force. Subject: "Recent Experiences of Artificial Respiration,

#### ORIGINAL PAPERS.

#### ON DILATATIONS OF THE FEMALE URETHRA. (a)

By R. D. PUREFOY, M.D., F.R.C.S. Formerly Master of the Rotunda Hospital, Dublin.

THE structure and anatomical relations of the female urethra are such that in the ordinary conditions of life it is much exposed to traumatism, and to this many of its pathological conditions can be traced directly or indirectly. When we reflect on the pressure and stretching of the soft parts which attend parturition, even in easy deliveries, our only surprise will be that urethral trouble is not a more common sequel to child-bed. On the present occasion I desire to direct attention to dilatation of the urethra and its attendant complications in the lower, middle, and upper third of the canal. In the first-mentioned position it is so often associated with prolapse of the mucous membrane that it becomes difficult to say which condition originated first. It is, perhaps, less common here than in the middle or upper third, and is often due to some abnormal growth of the urethral lining, either some neoplasm or inflammatory swelling, or, if Baker Brown be right, associated with stone in the bladder. It is sometimes, unfortunately, a sequel to mechanical dilatation. Dr. Skeene records a very interesting case where there was marked dilatation of the lower end of the urethra, without any recognisable cause. The

(a) Bead in the Section of Obstetrics Royal Academy of Medicine in Ireland, May 21, 1908.

patient was an unmarried woman, æt. 35, who suffered from displacement of the uterus and cervical catarrh, but had no urinary trouble whatever. On making an examination it was observed that the orifice of the urethra was widely patulous and the lower third of the canal funnel-shaped. The mucous membrane was healthy, and the patient suffered no discomfort. It was not possible to ascertain any history affording an explanation of the origin of the trouble.

The symptoms in this form are less marked than in the other varieties, and as there is not necessarily any derangement of function, little discomfort may be experienced unless there be inflammation or ulceration, when urination will probably be frequent and painful.

An extreme degree of these associated conditions, prolapse and dilatation, was observable in a middle-aged married woman amongst my extern patients at the Adelaide Hospital some years ago. On separating the labia, what at first sight appeared to be the introitus vaginæ was found to be the enormously dilated urethral orifice, surrounded by a fringe of prolapsed mucous membrane. The finger readily entered the urethra for nearly an inch. There was no incontinence of urine, but a complaint was made of weakness and bearing down. The application of strong nitric acid brought about marked narrowing of the opening and corresponding relief to the discomfort. In this case I think it highly probable that coitus took place through the urethra.

Dilatation of the lower third of the urethra is also found in association with congenital absence of the vagina, in which case it is most probably due to coitus taking place into the urethral canal.

Two other alternative plans of treatment remain open to us—(1) The use of the actual cautery, using a pointed instrument applied in such fashion that strips of healthy mucous membrane may intervene between the cauterised surfaces, and thus obviate the risk of undue marrowing of the meatus; (2) the removal of redundant mucous membrane by knife or icissors and careful suturing with catgut.

Ulceration of the urethra in its lower third, attended with dilatation of the canal, is by no means common; but a case of great rarity and interest, illustrating these conditions, was admitted to the Rotunda Hospital under my care in the year 1901. The patient was an unmarried woman, aged about 33 years, and in bad health. So far as was known her mode of life made it highly probable that she was suffering from syphilis. On separating the labia the introitus vaginæ was with difficulty located, owing to the enormously dilated urethral orifice, everywhere showing a red granulating surface, in the midst of which a funnel-shaped depression marked the course of the urethra. It is very remarkable that in spite of this extensive structural change the woman did not suffer from incontinence of urine.

Dr. West, in his interesting "Clinical Lectures on Diseases of Women," gives an account of six cases, apparently identical with the one just mentioned, which came under his care. Two of these were married women, who acknowledged to having suffered from syphilis; the remaining four were of unchaste life, one of them at the time suffering from a secondary syphilitic eruption.

These patients alleged that they had experienced painful and difficult micturition for periods varying from nine months to five years. The ulceration appears to begin at the orifice of the urethra, and to extend thence inwards towards the bladder, producing as it extends a great widening of the canal and a patulous state of it orifice, so that the finger tip can enter it with ease, while the surface is the seat of large, firm, indolent granulations which secrete a muco-purulent fluid, and, though not very tender to the touch, are highly sensitive to the passage of urine. Dr. West observes:-"I have met with this ulceration of the urethra independent of any other disease of the sexual organs; but have also observed it associated with unhealthy ulceration of the clitoris and nymphæ, and also the posterior commissure of the labia and the entrance of the vagina. When the disease has been of long standing I have seen the lower wall of the urethra represented by a dense cartilaginous substance, not unlike one of the lips of a hypertrophied and procident cervix uteri, and on two occasions I have been able to carry my finger along the whole length of the canal into the bladder." "Whether these cases are truly syphilitic, or whether they deserve to be classed more properly with the rodent ulcer, or lupus exedens, I am at present unprepared to say. In their management combined local and constitutional treatment was generally followed by improvement, not absolute cure. The use of the actual cautery in one instance was productive of signal benefit."

My patient's history and probable mode of living rendered the diagnosis of syphilis highly probable; but her impatience of the restraints of hospital life prevented me from having her sufficiently long under treatment to effect any marked change in her miserable condition.

We proceed in the next place to consider dilatation of the middle third of the urethra, which is more common than that of any other portion of the canal. In this form the anterior wall of the canal maintains its normal position, but the posterior, being distended, settles down, so that in time the urethra, instead of being a slightlycurved canal, becomes triangular, the upperanterior wall being the base, and so a sac or cavity is formed. The constitutional symptoms arising from these urethral troubles are the same as those caused by urethritis, and are not peculiar to this class of affections, and a careful physical examination will be requisite in every case. A digital exploration of the vagina will reveal to us the size and consistence of the swelling, and a sound or catheter passed into the urethra simultaneously will enable us to ascertain the thickness of the abscess sac and at the same time differentiate between dilatation and hypertrophy. In the earlier stages of this affection the urethra in front and behind the pouch is really or apparently contracted, but in some cases of the kind the upper part of the canal and neck of the bladder become dislocated downward, and finally the upper portion of the urethra may also become dilated. That the middle portion of the canal should most frequently suffer in the way we are considering is easily explained by its position and relations. The hyperæmia which attends pregnancy and the increase of tissue in these parts will probably disappear very slowly—indeed, very incompletely—after a protracted labour, owing to imperfect involution; and a long series of pregnancies,

however successfully conducted, will inevitably be followed by structural changes here.

Bozeman, in writing on the pathology of this affection, points out that it is frequently preceded and caused by narrowing or stricture of the meatus. I think he has exaggerated the frequency of the last-named condition and its causal relation to the widening higher up. On the other hand, we know that the posterior wall is apt to be pushed downwards and contused, while the upper remains in its normal position. The relaxation caused by this over-stretching of the urethral wall forms a small pocket in the canal, which becomes gradually dilated more and more by the pressure of the urine till urethrocele is fully developed. This presents itself as a smooth, round swelling of the anterior vaginal wall, having a sharply circumscribed outline, generally presenting at the vaginal entrance, especially if the patient coughs or forces. Pressure on this swelling causes diminution in its size and a flow of pus from the meatus. The number and variety of terms applied to swellings which agree in having the clinical character just mentioned, furnish ample proof that authorities are still divided as to their ætiology; but I believe the history of their origin and causation already given will hold good in most instances, especially as I am not aware that the condition has been met in a nulliparous woman. At the same time, the possibility of an abscess occurring in one of the crypts in the floor of the urethra, or in one of the lacunæ of Morgagni, must be admitted. It will be well to remember that an ordinary cystocele or a vaginal cyst in the anterior wall closely simulates urethrocele.

Whatever be their origin we divide these swellings, for practical purposes, into two classes--viz. those in which the sac communicates with the urethra by a small opening, and, secondly, those in which the sac is more a pouch due to extensive yielding of the posterior urethral wall, and forming part of the canal itself. In the former class the swelling may be present for a long time without causing much discomfort or any disturbance of the urinary functions; in the latter class, even at an early stage, there will probably arise frequency of urination and difficulty in the act. As a consequence of the frequency and the straining efforts which attend it, the bladder is apt to become injuriously affected, hypertrophy of its walls is likely to follow, and possibly, cystitis due to extension of the urethral inflammation. The forcing and straining efforts made by some of these patients while urinating are even greater than the mechanical obstruction appears to account for. Possibly this is due to the accumulation of urine in the urethra, which excites extra reflex action in the bladder and urethra out of proportion to the existing obstruc-To cases of this nature—i.e., those in which the entire posterior wall of the urethra has become weakened and dilated—the term urethrocele should be restricted, while we reserve for the former class the terms "suburethral abscess," "abscess of the urethra vaginal septum," or "urethral diverticulum." The French gynæcologist, Huguier, is believed to have described this affection in 1847, but we are indebted to Mr. Hey, of Leeds, an English surgeon of much earlier date, for an accurate account of a case and its successful treatment by a method which will still be found one of the best we can employ for the purpose. m free incision of the sac, the application of an antiseptic to its lining and the subsequent plugging of the sac with iodoform gauze. Stitching the edges of the opening or removal of a small portion of the sac wall will help to secure free drainage. The dissection out of the sac is a difficult proceeding, certain to be attended with considerable bleeding and sometimes followed by a fistula. Before resorting to radical treatment, as just described, we may in some cases try the effect of dilating the urethra below the sac and secure its daily emptying by pressure, and washing out with any mild antiseptic. Success has sometimes followed these measures.

Von Winckel, writing in 1886, mentions a case in which the patient herself used to empty the sac by applying pressure frequently, and by combining this proceeding, with the assiduous application of lead lotion, brought about a cure. Several years ago, amongst the patients attending my dispensary at the Adelaide Hospital a young woman sought advice on account of pelvic pain and distress. Examination showed that she was three months pregnant, and that the discomfort was due to a swelling involving the anterior vaginal wall and urethra. On careful investigation, what appeared at first to be merely cystocele was found to be dilatation of the urethra such as we are considering. Unfortunately, as so often happens in the case of extern patients, I was unable to keep her under observation long enough to test the value of any mode of treatment. Recently I was more fortunate. A lady, early in her second pregnancy, came under my care, and when making a vaginal examination on account of some vesical trouble I observed a small, smooth swelling, which at the time I concluded was a vaginal cyst. Her confinement took place in the country, and some months afterwards, owing to greatly increased pain and discomfort, she again consulted me. The swelling had considerably increased in size, and now presented unmistakable evidence of being an abscess sac communicating with the urethra. I dilated the canal anterior to the swelling, washed out the sac daily for some weeks, and effected such improvement that I hoped cure would follow. In this I was disappointed; so, several months subsequently, I incised the sac (which a more careful examination showed me communicated with the urethra by a small opening), swabbed the cavity with carbolic acid, and plugged it with iodoform gauze, having previously stitched its edges to the vaginal mucousmembrane to prevent too rapid closure.

I understand from my patient, who has returned to the country, that there is still some escape of urine when she moves about much. Even if there be a small urethral fistula, I am not without hope that it may close without further operative measures.

Kelly mentions that in one of his cases a secondary operation for fistula became necessary.

Dilatation in the middle third of the urethra is sometimes associated with the presence of a calculus, as happened in the case of a young woman admitted under my care into the Adelaide Hospital some years ago. It was situated apparently in a diverticulum in the anterior wall of the urethra, and so much overlapped by the mucous membrane that it was quite possible to pass a sound or catheter into the bladder without detecting its presence. With some trouble, after dilatation of the canal, I extracted the calculus. In such a case there is room for speculation as to the origin

of the calculus, whether it is renal or vesical, or even urethral, and simply arrested on its way down; or, on the other hand, whether it is portion of a foreign body introduced from without.

Dilatation of the upper third of the urethra is probably in most instances a consequence of a partial prolapse of the bladder and upper end of the canal, caused originally by injury inflicted during parturition, when the tissues are in a hyperæmic and relaxed condition. The condition of prolapse allows an unusual pressure of the urine upon the upper end of the urethra, and dilatation is apt to follow. From whatever cause arising, dilatation in the upper third of the canal may, and often does, give rise to very distressing symptoms. In addition to the frequent or incessant desire to pass water, may be added partial incontinence during coughing, laughing, sneezing, the effort to lift anything, or in stepping from a height. Without constant attention to cleanliness and the use of some soothing healing application inflammation of the outer parts will probably be added to the other miseries. Fortunately, in many of these cases the mechanical support which can be secured by carefully adjusting a pessary will afford considerable relief.

Some days after I had concluded my paper I unexpectedly found in the "Obstetrical Transactions" for 1890 a communication by Dr. Routh, headed "Urethral Diverticula," which deals with somewhat the same subject, and gives many interesting details of the various recorded cases. as well as the methods of treatment recommended and practised, including his own. It is not a little strange that he leaves unnoticed Mr. Hey's contribution to the literature of this subject, which is probably the first, and certainly one of the best, papers dealing with the affection. I am glad to find that he concurs in my opinion as to restricting the term urethrocele to those cases in which we find merely a dilatation of the canal; though he is too dogmatic when he states that palliative treatment invariably fails. I agree with him in rejecting the opinion that Skeene's ducts should be regarded as the anterior terminations of Gaertner's canals.

# RONTGEN RAYS IN DISEASES OF THE STOMACH. (a)

By V. SCHMIEDEN, M.D., Professor of Medicine, University of Berlin.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

In November last I delivered an address with demonstrations on this subject, "The Röntgen Rays in Diseases of the Stomach."

It is my intention to communicate some special experiences on the subject made in another place, and in my address, therefore, I confined myself to schematic tables, to show the typical changes of form; then showing a number of plates, in which the diseases of the stomach that caused changes of form could be recognised; the material was divided into cases of gastroptosis, dilatation, carcinoma, and hour-glass stomach. In discussing the schematic figures, I could only with a few words touch upon the interesting question, what form and what position, when empty and when full, were the characteristics of the stomach, as well as in the various phases of digestion—a question to which Röntgen illumination has contributed im-

(a) From observations carried out in Professor Bier's Department of the Royal Surgical Klinik, University of Berlin. portant conclusions. There was not time to go into the importance of these conclusions as regarded general stomach diagnosis, nor into the method of examination, nor the natural limits with which it is hedged in. It was for me to show that to him who is able to look over a large field of observation, and who is able to control what he sees by operation, a surprising amount can be shown in the Röntgen figure, and very rapidly and plainly, quite independent of the question as to how much could have been discovered without the aid of the Röntgen rays.

In the discussion that took place, some speakers put forward the question whether any real advantage was to be hoped for from the procedure or not, so I am compelled to give expression to my own views on the point, as well as to make known the method of examination, which the shortness of time on the previous occasion did not allow. First of all, there are many more aids to the procedure than could be mentioned at the session of November 12th. I have only shown pictures obtained by dorso-ventral radiography in the upright position; 500 grm. of porridge were given previously (a smaller quantity in case the stomach was small) mixed with bismuth. The first taken was made immediately after filling the stomach; a second, or perhaps a third, from two to seven hours later. In this way it is shown, for example, that some hours after the filling of the stomach it was completely emptied by way of the pylorus, or that for twenty-four hours considerable portions of the bismuth mixture still remained in it. In this way important conclusions could be drawn, not permitted in so simple and decided a way by any other clinical method; the form and changes of position of the shadows were not only interesting, but also of high value. I here call to mind the changing and filling of the two halves of an hour-glass stomach, of which I have now made seven observations, and, above all, the clear images caused by remains of bismuth in the crater-like depressions of ulcerated carcinomata, and which could be seen there when all the other parts of the stomach were free. Such residua have sometimes given a better indication as to where the growth actually was, and how far it extended, than when the stomach was

In this connection the question may well be asked whether in the great majority of cases such a special diagnosis as to the site of the tumour is of much importance as regards therapeutics? No true critic can answer such a restricted question with a "Yes." We know that for the question, with a "Yes." We know that for the question, "Operation or not?" a much more general diagnosis is sufficient; yea, even that the experienced surgeon in many cases, when the history is known, can tell by even a little handling whether laparotomy must be performed or not. In such cases— and they are not a few—we can put into practice the whole of the apparatus of internal diagnosis, which consists in testing the residua of the stomach contents-the test breakfast, chemistry, examination of the stools, the constitution of the blood, and many other things. And in spite of this labour, in any well-ordered hospital a part of these diagnostic aids, at least, will be made use of, because every scientifically-working surgeon desires to secure himself against surprise, because he will keep his knowledge and action under control, and, not least, because we all know that these aids sometimes bring up unexpected information and clear up errors of diagnosis. Above all, then, a teaching institution must make this its standpoint.

But the above-named question, whether there is any value as to treatment, in the great majority of.

cases does not touch the central point of the matter. In the first place, a very accurate diagnosis must be striven for for its own sake, independent of any ponderable use in any given case; secondly, we must thankfully acknowledge that the Röntgen procedure has in individual cases given us certain conclusions when all other means have left us in the lurch. This is the case, for example, in the case of tumours that cannot be felt, that hide themselves under the liver, especially at the lesser curvature, and which sometimes cannot be demonstrated until it is too late for operation; or the high-seated hour-glass stomach, which every experienced surgeon knows is frequently only brought to light by the laparotomy itself. Such cases are known to other observers also, and in the discussion mentioned, Goldscheider related such a case that was not recognised until it was submitted to the Röntgen rays.

At the klinik at which the above-named studies were made, the greater part of the stomach cases were taken direct from the poliklinik, and only a small part from the hands of the intern specialists, who had already made thorough previous examinations. We are, therefore, thoroughly schooled in making use of all means of diagnosis, and are far removed from putting radiography in their place. In addition to the history of the patient, we make use of a diagrammatic sheet, in which all points for inquiry are scheduled. These embrace age, sex, occupation, history, as to pain, eructations, vomiting, hæmatemesis, emaciation, melæna, appetite, constipation, palpation, gaseous distension, examination of residua of food, trial breakfast and its chemical examination, condition of stools, Röntgen illumination, after giving bismuth and porridge.

This shows that in making use of the Röntgen process we do not dispense with other means of diagnosis; we use it for the purpose of completing, but not excluding.

I consider it unfortunate that the importance of radiography for diseases of the stomach, about which there can no longer be any doubt, is kept in the background by people saying that the practising surgeon has not always an X-ray apparatus at his command. If so, the Röntgen rays should not be used at all, and, more than that, on the same grounds, a large number of scientific aids would be excluded from the clinical laboratory, such as bacterial and serological diagnoses, and many others, as the practitioner has neither the time nor the special skill, nor the apparatus necessary for all these.

Along with the photography of the stomach, the direct view before the Röntgen screen is of great importance, from many points of view; greater than the plate figure. It is true that the illumination of a large corona cannot be carried out. With some practice, we see how the mouthful swallowed glides down before the eyes, forms itself to the shape of the stomach's interior, where it makes a halt, for example, at a contracted spot; we see also whether in the flaccid, atonic stomach it sinks at once into the deepest part of the greater curvature.

At the same sitting we can also see the gas bubbles that are always to be found at the fundus of the stomach, the form of which is of diagnostic value, and the size increased by taking an effer-vescing draught. The movements of respiration alter the position of the diaphragm and the abdominal contents; drawing-in of the abdomen acts in a similar manner. In certain forms of the stomach, or when adhesions are present, the bismuth law is sometimes pushed upwards,

sometimes downwards, and sometimes there is no change. At the greater curvature the eye sees the form and character of the peristalsis; the bismuth mixture may be pushed in any direction by the hand, towards the pylorus, the function and behaviour of which towards the stomach contents may be studied. In the address mentioned, examination in the dorsal or lateral position could be just as little touched upon as all this, and they are all methods for refining the diagnosis. There is also the combination of illumination with palpation of a tumour that can be felt, and its relation to the bismuth shadow.

With these short notices I would bring to your view the many-sidedness of the procedure. In difficult cases the most diverse ways are attempted to gain light on the diagnosis. Illumination most suitably follows an examination made with the screen; the image seen here is sketched with a fatty pencil and compared with that produced on the Röntgen plate.

As is known, our method of examination is not applicable to the stomach alone; the cesophagus and the intestinal canal are within certain limits accessible to it, and beautiful sharp contrasts arise in considering the deep shadow against the air-filled colon and the small intestine. It is possible for the practised eye to distinguish tumours of the stomach from those that belong to neighbouring organs, and which only affect the contour from without. It is just in these difficult cases that one learns to understand how foolish it would be to depend for a diagnosis in difficult cases on the Röntgen image alone. I designedly omit going into details here; these can only be discussed in connection with the individual case when we have the illustration before the eye.

Neither shall I go into the question of the technique employed in producing the illustrations shown at the meeting mentioned. For the coarse outlines of the stomach a time exposure is sufficient; for the more delicate contours the so-called flash pictures are best made use of (that is, exposures of about 4 seconds); they come out more sharply, as the movements of respiration and peristalsis do not blur the picture. In tumours attached to the abdominal wall or the pancreas, also, a time

exposure gives the sharpest picture.

It is perhaps too early to bring up the question as to whether the Röntgen light will be called upon to render the long-desired early diagnosis of cancer of the stomach possible, or, at least, to allow of more timely conclusions to be drawn. I hold the latter to be possible in individual cases; it will certainly be very useful. On the whole, however, one hopes at present in vain. I promise myself some advantage from the above-mentioned illustrations, in which the deposits of bismuth have remained in a suspicious spot in the stomach, whilst the remainder of the porridge has passed on. Attempts should repeatedly be made to get such a picture in a similar case, just as one recognises a renal calculus by a constant shadow by observations made on several days. This, however, would not unconditionally prevent confusion with ulcer of the stomach. The change of form produced by a commencing carcinoma would in many cases be exactly that produced by an ulcer, and we also have learnt by experience that a possible source of error lies here. It would lead astray, not to mention the deceptive images that will certainly make their appearance, especially in the case of the beginner. Since the introduction of the bismuth method, however, we have expected greater things, and more special diagnoses than formerly. This speaks more for the value of the method than for its uselessness. For reasons easy to be understood, the method has quite well-defined limits, as a portion of the diseases of the stomach are not attended by any characteristic change of form that can be represented by any means at our command at present. The Röntgen procedure is every year making such great strides that there is no ground for placing limits on what it can do. For the last six months I have applied myself to this method, and have examined about fifty cases; every case brings new original observations and advances our experience. It has already been of great practical use. We believe that surgery will reap the main advantage from it, as the true and the false figures can at once be controlled, and as the shadow figure often leads at once to the diseased part of the stomach without any lengthened search.

I would point out, in conclusion, that the clear plastic image allowed by the bismuth method makes it an excellent educational means for academic instruction.

THE

# PREVENTION AND TREATMENT OF DYSENTERY. (a)

By Lieut.-Colonel W. J. BUCHANAN, M.D., B.Ch.,

Inspector-General of Prisons, Bengal,

THE subject of the prevention and the treatment of dysentery is one of great importance. It is probably a more common disease in Bengal than in other parts of India, so much so that Norman Chevers, an acute observer, many years ago, applied the term "Morbus Bengalensis" to the chronic ulceration of the intestinal tract from which so many natives of Bengal die.

The successful prevention of dysentery must depend upon an accurate knowledge of its ætiology and method of spread. In typhoid the view has recently been taken that it is the sick or convalescing patient that is the danger, the "bacillus-carrier," and Capt. Forster has brilliantly applied this theory to dysentery. We have therefore been endeavouring to fight dysentery in Bengal gaols on these lines. The bacillus of Shiga or other allied bacilli are the causes. These organisms are shed by the convalescing or sick "carrier," and reach the intestinal tract of other persons in many ways.

I am, however, firmly convinced that the predisposing causes are of great importance, and they have the advantage that they are, to a considerable extent, controllable. Moreover, in considering such a disease in 'a gaol, asylum or school we must remember that a very considerable number of the inmates bring the disease with them from outside, and are therefore actual or potential "bacillus-carriers" from the moment of their admission.

The Predisposing Causes.—Among the predisposing causes must be counted the disturbance of the digestive tract caused by unsuitable fcod, or badly cooked food. The danger of badly-cooked food was forcibly impressed upon me some 17 years ago in Midnapore Gaol, where, after a violent cyclone had wrecked the kitchen, the prisoners' food that evening and the next morning was issued in a raw, half-cooked state and there was within the next few days a sudden outburst of dysentery and diarrhœa, 125 patients having been

admitted to hospital within a couple of days. On many other occasions, seeing a rise in the number of dysentery cases coming to hospital, I have directed attention to the cooking and almost always found something wrong. I am therefore firmly convinced that good cooking and well prepared clean food are important measures in the prevention of dysentery. Other predisposing causes are less direct, for example, previous illness, malaria, etc. Food, however, I am convinced is more important than water. It is a commonplace of hygiene to put down bad water as a cause of dysentery, and certain specific cases are always quoted. I have long held the following view (and it applies largely to typhoid also) which is that water if specifically polluted will carry the disease, and will account for a sudden outburst of dysentery or of typhoid, but such outburst will be short-lived and will cease or greatly lessen on changing the water or on destroying the virus by boiling, etc., but the water supply will not explain the persistence of a few cases of dysentery or of typhoid; and the supply of pure water will not get rid of these diseases, and that even where the greatest care is taken of the water. Even where it is carefully filtered in a Pasteur filter installation and distributed in pipes dysentery may still prevail.

The water-borne theory of typhoid conveyance has long been known to have broken down in India, and I have long come to the conclusion that elaborate care taken of the water in gaols is not the cause of the diminished incidence of dysentery, and that it has prevailed in gaols with a water supply above suspicion, and has not prevailed in gaols and at times when the Chemical Examiner could only classify the water as "suspicious," or at best "usable." It is very probable that the dysentery bacilli soon die in water. Another factor in the spread of dysentery in a gaol or an asylum is by means of soiled clothing and bedding. Capt. Forster's work at Midnapore shows that the Shiga bacillus has a short life outside the human body, and on clothing and on sheets the bacilli have been killed by exposure to the sun in a couple of hours.

Means of Prevention.—Once we get hold of the view that it is the convalescing or sick dysentery patient that is the danger and that for several weeks after apparent recovery he may be, and probably is still shedding the bacilli in his stools; it is not difficult to suggest means for prevention. The latrine, for example, may become an important factor in the spread of dysentery, and the use of the left-hand by natives of India for ablution is also an obvious source of infection and reinfection. The free use of dry earth by each prisoner is one safeguard, the burning of sulphur or cowdung to keep off flies is another precaution, as also is the use of kerosene in the limewash in latrines.

I need hardly go into further details, the main point is to recognise the principle that the sick or convalescing dysentery patient is himself the danger to others, and he should be looked after, especially as long as he is shedding bacilli in his excreta. Just as we are accustomed to look after and isolate convalescing small-pox or scarlatina patients while they are shedding the germs from the skin eruption. I do not say that it is easy even in a gaol, to carry out a full prophylaxis. Difficulties as to safe custody, work and discipline arise, but it is well worth persevering in the strict

isolation of these "bacillus-carriers," even at a temporary loss and with considerable difficulty. This method will certainly soon reduce the number, and the more thoroughly the method is persevered in, the more certain is the reduction in number, and consequently the less the difficulty.

The question of the new-comer remains. The population of a gaol is eminently a floating one, and about as many come in as pass out. Hence there is a constant stream of new-comers, many of whom are potential or actual "bacillus-carriers." We have not the means, it is needless to say, of conducting a bacteriological inquiry into the case of each new-comer, we must assume that all may be or are "bacillus-carriers," and make use of the seven to ten days of compulsory segregation to treat them with prophylactic doses of salts and perchloride of mercury, so as to get rid of as many as possible of the bacilli before the prisoners are allowed to mix in the general file.

I therefore advocate these measures of prevention as a convinced adherent of the view that sick and convalescing patients are the "bacillus-carriers," and are the danger especially to guard against, and I believe that once we grasp this essential fact it is not difficult to devise means of counteracting the evil influences. At first, no doubt, the action, necessitated by an acceptance of this view, is troublesome to enforce, but the more it is enforced the easier it becomes, and perseverance will certainly be rewarded.

#### OPERATING THEATRES.

ST. MARY'S HOSPITAL.

REMOVAL OF ANGIO-FIBROMA FROM LEFT VOCAL CORD.—Dr. WILLIAM HILL operated on a man, æt. 30, who had been sent up to the hospital by Dr. Baron, of Bristol, with a history of hoarseness of very long standing. There had been complete aphonia for five standing.

Chloroform having been administered, a direct vision laryngeal tube was inserted, and by this means the glottic region and the growth were brought into view at a distance of 6 or 7 inches from the eye of the observer. A straight pair of punch forceps were then introduced, and the growth, which was the size of a split marrowfat pea, completely removed by one manipulation of the instrument.

Dr. Hill pointed out that the removal of growths

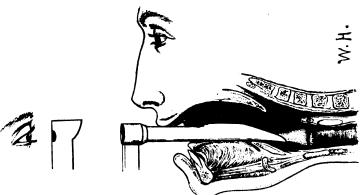

Diagram to show position of Brüning's laryngeal tube-spatula, with distal end in laryngeal vestibule, preparatory to removal of growth from vocal cord. For the sake of simplicity Brüning's hand-lamp is not shown.

in the near neighbourhood of the anterior commisure was always difficult under the old indirect mirror and forceps method, and often necessitated a large number of sittings to train the patient to toleration. All sorts

of difficulties, too, were encountered when the patient was over-sensitive and had no fortitude. With the was over-sensitive and had no fortitude. method he had just employed the patient comes into hospital one day with a growth, and minus a voice, and leaves the institution on the next day minus the growth and plus his voice. In expert hands, he said, the operation is performed without apparent difficulty, but it is not as easy as it looks to the spectator, as exactness in points of the technique of the operation is absolutely essential to success. He remarked that the direct method of operating on the larynx had been introduced by Kirstein twelve years ago, but had been little practised in this country till within the last year or two. During the preceding fifteen months, he said, a considerable number of endolaryngeal operations for the removal of growths had been performed in St. Mary's Hospital, but in no instance had the old indirect method been resorted to. Deep chloroform anæsthesia, he asserted, was essential, gas and ether being contraindicated on account of the spasm and congestion they caused. The operation is much facili-tated by painting the larynx with a solution of adrenaline and cocaine before the administration of the chloroform, and again previous to passing the instrument. In some instances the operation can be carried out entirely under cocaine anæsthesia alone. The chloroform should be administered by a skilled anæsthetist, as very deep anæsthesia is required to ensure perfect steadiness of the larynx and pharynx.

On the next day the patient quitted the hospital. His voice was then normal.

#### TRANSACTIONS OF SOCIETIES.

THE ROYAL SOCIETY OF MEDICINE.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

MEETING HELD FRIDAY, MAY 28TH, 1909.

Mr. R. CLEMENT LUCAS in the Chair.

THE following resolution, sent up by the Council of the Section, was passed by the meeting:

"That, in the opinion of this Committee, it is desirable that the Board of Education should issue forthwith a complete set of forms for use in the medical inspection of elementary school children, in accordance with Circular No. 582, issued by the Board on January 23rd, 1908, and should issue definite instructions to medical officers as to the manner in which the medical inspection shall be carried out."

The following cases were shown:—
Dr. Porter Parkinson showed a child, æt. 4, with a large tumour on the left side of the abdomen extend-

ing to the iliac crest and nearly to the mid-line. The child had been healthy until a fortnight ago. Dr. Parkinson believed the mass to be a cystic malignant growth probably starting in the kidney.

Dr. F. LANGMEAD showed a case of

FACIAL IRRITABILITY OF FIFTEEN MONTHS' DURATION,

succeeding tetany, in association with dilatation of the large intestine. The girl æt. 8, was admitted to hospital for tetany in April, 1908. Her facial irritability was pronounced on both sides. No signs of organic nervous disease were found. The colon was dilated. Attacks of laryngismus stridulus occurred. The urine contained indican. The colon was daily washed out, whilst castor oil and salo! were given by the mouth. Sauerin,

koumiss, and thyroid were also used without effect. The washing out was discontinued, and energetic treatment with bismuth and opium applied. Enemata and massage were then used for a week with improvement, and after two months

she had gained 4 lb. in weight, and the tetany and laryngismus had subsided. The massage was continued for three months. The signs of dilatation of the colon then disappeared, but the facial irritability persisted. A month ago she had another attack of tetany with vomiting. Dr. Langmead referred to nine cases exhibiting relapsing tetany, dilated large intestine, and unhealthy offensive motions, occurring at an age beyond that of the usual infantile tetany. All had died except the patient exhibited. On tapping the cheek of the child an immediate rapid contraction of the muscles on the same side of the face was elicited.

Dr. ROBERT HUTCHISON asked whether the tetanic condition had ever been observed in congenital dilatation of the colon?

Dr. LANGMEAD replied that the question was

Dr. C. CARPENTER showed:—(1) A specimen of hypertrophic stenosis of the pylorus removed from a three-weeks old female child. The child was sick after taking the breast for the first time, and after every feed for a fortnight. A mixture of barley water and milk was used without success. The child when brought up was not in a fit condition for surgical operation. (2) A specimen of morbus cordis with complete transposition, including the liver, spleen, and large intestine, with a cyst in the tongue, and a solitary kidney. The condition was not diagnosed during life, and no symptoms were observed pointing to heart disease. The child became worse, and had fits two days before its death. (3) A specimen of congenital dilatation of the colon. This was from the colon of a child shown at the April meeting of the Section, at which the diagnosis had been questioned by some of the members.
The later history was that at the beginning of May she began to waste suddenly and quickly, losing 3 lb. 6 oz. in one week. Septic sores developed on the fingers. The bowels were opened regularly by cascara; the motions were of a pultaceous nature. As the infant became more and more wasted, the enlarged colon was readily seen through the thin abdominal wall, and contraction was easily excited by flipping with the The colon is about 17½ in. in length, and in. in circumference at the widest parts. The finger. The colon is about 17% in. in length, about 5 in. in circumference at the widest parts. dilatation begins at the ileocæcal valve, and ends abruptly at the beginning of the rectum. The mucous membrane shows no ulceration.

Dr. Spriggs said he was one of Dr. Carpenter's critics on the former occasion solely on the ground that the X-ray photograph was not, in his opinion, conclusive, and he was prepared to adhere to that view, though there was no doubt that the colon now produced was dilated.

Mr. CLINTON DENT gave a cinematograph demonstration of the movements of the stomach, as seen through the abdominal wall, in a case of

CONGENITAL HYPERTROPHIC STENOSIS OF THE PYLORUS.

The child was aged 8 weeks, and it weighed 8 lb. on birth, and 5 lb. on admission to hospital, 11 days before death. It was not considered safe to operate. The pylorus could be felt distinctly; gastric peristalsis was extremely marked and very easily excited. The cinematograph showed plainly the waves of contraction passing over the stomach. Mr. Dent said that the post-mortem examination showed the whole pyloric canal to be in a state of hypertrophy. The mucous folds were well marked, and, he had no doubt, were, as is usually the case, the final cause of the obstruction.

The CHAIRMAN expressed the indebtedness of the Section to Mr. Dent for his excellent demonstration.

Dr. ERIC PRITCHARD showed:—(1) A case of unilateral hypertrophy of the hand from macrocheiria in a boy, æt. 10. The left hand was observed to be larger than the right shortly after birth. A capillary nævus was also noticed to extend in an irregular manner up the arm and down the left axilla. The hypertrophy of the hand appears to have been progressive, but sometimes it is more swollen than at others. No similar condition has been observed in any other member of the family. The left hand is larger than the right in the ratio of 9 to 5, as determined by displacement of water. The length of the hand from the fold of the wrist to the tip of the middle finger is

6 in. in the left and 5½ in. in the right, and the breadth is half-an-inch greater in the left. The colour is purplish. The hand looks as though it is ædematous, but does not pit on pressure. The muscles appear to be feebly developed. On X-ray examination the bone appeared normal. There appears to be a lymphangiomatous element in the general hypertrophy. Dr. Pritchard regarded the hypertrophy as due to the increased blood supply dependent on this condition.

The CHAIRMAN agreed that the condition was nævoid. Dr. PARKES WEBER thought it was better to class such cases as angioectatic hypertrophy, because the hypertrophy might involve the venous vessels or the arterial vessels, or the lymphatic vessels, or any combination of the three.

Dr. PRITCHARD also showed (2) Symmetrical helical fistulæ, with branchial fistula in an infant. The case resembled one shown by Mr. Howell Evans at the June meeting, 1904. It showed two symmetrical fistulæ at the anterior aspect of the helix of the ear, about 2 mm. in diameter, and the same in depth. At times they emit a thin secretion. On the left side of the neck, at about the level of the anterior margin of the sterno-mastoid muscle, is a small depression representing in the usual position the vestigial remains of what was once a branchial cleft. In front of the right ear there is a small nodule or pre-auricular tubercle. No other stigmata were shown. Similar helical fistulæ have occurred in several members of the family. The mother, who was present, showed them on both ears, and so did four of her children, deceased. The maternal grandmother and two of her sisters also had symmetrical helical fistulæ.

Mr. A. J. ROOTH and Mr. J. HOWELL EVANS showed a case of

#### CONJOINED TWINS.

Mr. Howell Evans said that Mr. Routh had attended the mother of the twins, but they were born before his arrival. The method of presentation seems to have been normal, the cephalic position for the first child, the legs of the second child then came down, and the birth was accomplished. They belonged to the type of twins which had survived longer than any other-namely, those joined by the buttocks. The radiograph suggested that they were joined with more than fibrous tissue. Though the female genitalia were complete, there was one common anus, the rectum of the second child opening into the rectal ampulla of the first. The mother was one of twins, and there had been other twins in her family. Several members of the father's family had had congenital heart disease. The twins were now about a year old. Conjoined twins of this nature had lived to considerable ages. The only illness suffered had been bronchitis, which began in one child. Medicine was administered to both, but, in spite of this, the second child also had bronchitis. Separation had not been attempted on the ground that the twin which seemed to be weaker appeared to have the greatest amount of alimentary canal.

Dr. G. A. SUTHERLAND showed, for the second time, a case of cirrhosis of the liver in a boy, æt. 11. Ascites had recurred, and 150 oz. of clear fluid had been drained off, since when tapping had been re-peated at intervals. Of late he had been tapped about once in ten days, about 200 oz. of fluid having been drawn off in each case. Fresh spider nævi have developed on the face and extremities. The liver can be felt about half an inch below the ensiform, and The spleen extends about 11 in. below nowhere else. the costal margin. The temperature often rises to 100° at night, but there are no signs of tuberculosis to be obtained. He has had seven doses of fibrolysin without any effect at present. Dr. Sutherland asked whether the surgeons could recommend omentopexy, as the case was one of chronic recurring ascites.

The CHAIRMAN asked what Dr. Sutherland thought vas the cause of the condition, and what was the condition of the heart?

Dr. SUTHERLAND replied that there was no evidence of adherent pericardium. He did not know that syphilis had been excluded, but mercurial treatment as a method of cure had been tried in vain. Still, in advanced cases of syphilitic liver, this would be the

case. The mother died two years ago of alcoholism, but there was no evidence of the patient having been given alcohol.

Dr. G. A. SUTHERLAND showed two cases of CEREBELLAR ATAXY

The first was a child, æt. 4, who had never learned to walk properly. Her gait was ataxic. There is imperfect co-ordination of the hands, the finer movements of the fingers being defective. The mental condition is considered normal, but temper very bad. Sensation is normal. The knee-jerks are very active, the plantar reflex shows a flexor response. There is no nystagmus or fundal change. The second case is a female, set. 21, sister to the above. She has never learned to stand or walk, can sit up, but always sways about and has irregular jerking movements. She has a vacant look, arregular jerking movements. She has a vacant look, and her speech is not very intelligible. There is no nystagmus or fundal change. The muscles are hypotonic. These are the only children of the family. The symptoms suggest imperfect development of the cerebro-cerebellar system, and more especially of the cerebro-cerebellum. There is no history of syphilis.

Mr. Sydney Stephenson showed a case of

OXYCEPHALY in a boy, aged 32 days, who was admitted to hospital with ulceration of the right cornea. The right eyeball protruded from between the eyelids immediately after birth. The labour was easy. The eye bulges forth birth. The labour was easy. The eye bulges forth whenever the baby screams or is bathed. The child weighed 5 lbs., had a red and wrinkled skin, loud "snuffles," and a slight papular rash on the hands and arms and trunk. The skull is typical of oxycephaly, the frontal region rising steeply and overhanging the face. The cranium is deficient as regards total size and capacity. All the bones and sutures appear to be present. The eyeballs, especially the right one, are prominent, though they can still be covered with the eyelids. The orbits are clearly deficient in depth.

The Chairman said that those interested in such

The CHAIRMAN said that those interested in such cases as this might like to know that at the Royal College of Surgeons all the abnormal skulls had been

College of Surgeons all the annormal skulls had been arranged in series by the new Curator, Dr. Keith.

Dr. H. MacCormac showed a case of congenital laryngeal obstruction in a girl, aged 5 months. The infant was brought to hospital on account of a "cough from birth." On examination, there was a faint purring noise to be heard during quiet breathing, which became more evident on forcible respiration. The mother said that the condition had existed since birth, that it seemed to produce no inconvenience, and that it disappeared during sleep. No physical signs of pulmonary disease were found, nor was there any indrawing of the lower part of the thorax.

Dr. PARKES WEBER read a paper on CONGENITAL OBLITERATION OF THE BILE DUCTS WITH

HEPATIC CIRRHOSIS.

The patient, a boy, aged 3 months, was admitted to hospital suffering from malnutrition and jaundice of moderate degree. The mother said the child had been jaundiced from birth. No other member of the family had jaundice. The mother had had no miscarriages. The child's liver was enlarged, but not tender. riages. The child's liver was enlarged, but not tender. The faces were acholic and rather copious. The urine contained bile pigment and one or two granular casts. Blood examination: Hb. 90 per cent., red cells 3,900,000, white cells 9,400. Differential count (made by Dr. J. C. G. Ledingham): Polymorphonuclears 61 per cent., large lymphocytes 26 per cent., eosinophils 3 per cent., small lymphocytes 1 per cent. In a month the child had gained one pound and the jaundice began to diminish. The spleen, however, had increased in size for its lower border could be felt one inch below after two months in hospital the temperature was frequently raised to 101° or 102°. At the age of five months convulsions set in and the child died. Necropsy: The gall-bladder was represented by a fibrous scar, and the common bile duct was hardly pervious. These congenital changes were doubtless partly inflammatory in origin, and, as usual, were un-accompanied by congenital defects elsewhere in the body. The hepatic cirrhosis was found to be chiefly of interacinous distribution, and was doubtless to some extent a result of the Abstruction.

Dr. H. D. Rote and that Dr. Weber's case

aid that Dr. Weber's case

differed from the ordinary run of cases of congenital obliteration of the bile ducts. The distribution of the fibrous tissue was different, and there was a curious condition about the enlarged glands in the portal fissure in that they were matted together and that there was practically a stricture produced in the portal fissure by an inflammatory condition outside the ducts. The question arose as to whether it might be a case in which the obstruction of the ducts was produced outside the ducts. The only point against that was the practical obliteration of the gall-bladder. His own belief was that there was no congenital narrowing of the ducts at first, but that from the beginning it was an inflammatory toxic process. This was contrary to the view upheld by Dr. Thompson and advocated in America.

Dr. G. CARPENTER said the question, in his mind, was whether syphilis had any part in the causation of obliteration of the bile ducts, and he quoted two cases which had been under his own observation in which there was no doubt that syphilis was present. In a third case there was no evidence of syphilis. In this the cystic duct had been obliterated, and the gall-bladder was full of bileless mucus.

Mr. RALPH THOMPSON read a paper upon congenital dislocation of the hip-joint and showed a number of specimens clearly illustrating the points which arose. He put forward the view that the changes associated with pressure or static dislocation of the hip are too frequently regarded as primary and as producing the dislocation, whereas in many cases of congenital dislocation no deformity is noticed until the child begins to walk, and the deformity occurs in well-developed female children in whom the mechanical conditions are more likely to produce dislocation at the time of the adoption of an erect attitude than is the case in males. The changes found are a shallow and triangular acetabulum, a small flattened head of the femur with a short and anteverted neck, deficiency in the iliac segment of the acetabalum and hour-glass constriction of the capsule, a stretched or absent ligamentum teres and some coxa valga shortening of the leg below the knee. These conditions could all be explained by considering the mechanics of the joint in children of two to three years. Mr. Thompson gave full demonstrations of these points.

Thompson gave full demonstrations of these points.

Mr. Hugh Lett said the Section was very much, indebted to Mr. Thompson for his paper, which had evidently been produced with a great amount of care, and entailed much work. The theory he brought forward was interesting and important. All whohad seen cases of congenital dislocation of the hip must have been struck with the remarkable fact that those children did not appear to have anything wrong until they were three or four years of age. No-called or anything of the kind had been noticed: simply that the child had perhaps limped ever since she could walk. He would like to consider the paper more carefully before speaking decidedly about it; but there was much, from an anatomical point it; but there was much, from an anatomical point of view, in what was brought out, particularly in connection with the foctal pelvis, and the relations of various lines of force in male and female. He believed Mr. Thompson's view would be accepted by many authorities, and those who did not accept it would be bound to weigh it with great care before putting it on one side.

The CHAIRMAN said he had been accustomed to point out that when a child had been taken off its walking on one limb, from any cause, not only the thigh but the feet and all the bones of the limb were shortened from the lack of use. He understood from the argument that as the female was less protected than the male from dislocation of the hip, it was unwise to place the female child on her feet so early as the male

> CENTRAL MIDWIVES BOARD. MEETING HELD JUNE 24TH, 1909. Dr. CHAMPNEYS in the Chair. PENAL CASES.

Two women were cited to appear before the Board. One of them was charged with persistent failure, after repeated warnings, to notify the fact of having called

in medical aid. The other, Emma Pitman, who appeared in person and was defended by a solicitor, was a complicated case. The principal charges against her were those of false entries in her register-two cases which appeared there as having been given up "doing well" having died. Dr. Stephenson, Medical Officer for Bridgwater, and Dr. Hartnoll, who had been called into one of these cases, gave evidence. The Bridgwater District Nursing Association, from which Dr. Hartnoll had obtained a nurse to attend the second case, refused to allow the nurse to give evidence, a point which was commented upon by the Chairman as increasing the difficulties of the Board and neglecting a public duty. The scanty evidence which was forthcoming showed the midwife to have failed to realise the serious condition of these two patients. One she had left two days before her death, thinking her to be going on all right. The other she found, four days after confinement, in a condition which she attributed to worry and lack of food and firing, and did not call in medical assistance. A few hours later when the doctor was called in by the nours later when the doctor was called in by the husband, he found her semi-comatose, with a temperature of 103°, and suffering, in his opinion, from septicæmia. She died the following day, and Dr. Hartnoll, signed the certificate of death in accordance with the foregoing symptoms. He did not, however, notify the case within the prescribed time, nor warn the midwife, with the result that she continued to practice without disinfection. The woman was severely censured. and disinfection. The woman was severely censured, and a report of her work was to be asked from the local supervising authority in three, and again in six months.

GENERAL MEETING. At the close of the penal session the usual business of the month was dealt with. Letters had been received from Dr. Thresh, County Medical Officer for Essex, and Mrs. Gifford, Hon. Secretary of the Oldham, Copford and Mark's Tey Nursing Association, as to the refusal of medical practitioners to attend when summoned on the advice of a midwife. The Board replied that no blame could be attached to the midwife if she strictly carried out the rules as to summoning medical assistance. In reply to requests from certain training schools and nursing associations in Devon and Cornwall, it was agreed that the written part of the examination might be held locally, subject to an undertaking being given to observe the terms and conditions fixed by the Board as to the conduct of the

The Board appointed Clifford White, M.D., M.R.C.P., F.R.C.S., on the list of Supernumerary Examiners. The following were approved as teachers:—John Singleton Darling, M.B., Samuel Charles Collingwood Fenwick, M.D., Thomas Thomson Rankin, M.B.

A letter was read from the General Secretary Medical Defence Union as to a certified midwife prescribing for a patient suffering from influenza, and appending the initials C.M.B. to her name.

In reply, it was agreed that the Medical Defence Union be informed that the midwife has undertaken to discontinue the use of the initials C.M.B., and that it does not appear from the evidence before the Board

nt does not appear from the evidence before the Board that the midwife has prescribed. Her name was merely appended to an advertisement for powders.

At the last examination for the certificate of the C.M.B. the number of candidates was 607, considerably exceeding any previous number. Of these, 495 passed, making the percentage of failures 18.5.

The next meeting of the Board will be on July 22nd.

### CORRESPONDENCE.

#### FRANCE.

Paris, June 27th, 1909.

TROUBLES OF THE MENOPAUSE.

THE hygiene and treatment of the menopause is directed towards possible complications. The change

of life is frequently a troublesome physiological condition, but it is not a malady.

A treatment which has come into vogue these recent years consists in administering by the mouth or sub-cutaneously ovarian extracts of animals. By this-method—organotherapy—an attempt is made to restore to the woman in a sort of artificial way the useful principles lost by the normal cessation of the functions of the ovaries. A certain relief is in reality obtained, as assured by Jacobs, of Brussels, under the following conditions :-

(1) The troubles of the natural critical period disappear or are notably improved by ovarian extract.

(2) The same results are observed in the troubles experienced after surgical operations on the female organs with more or less mutilation.

(3) Anæmia of young girls and that following delivery or operation disappears rapidly by ovarian injection.

(4) Certain cases of grave mental disturbance are

definitely cured by this treatment.

Against nervous trouble, vertigo, sensation of heat, valerian or the bromides are useful:—

Bromide of potassium Bromide of sodium 21 dr. Bromide of ammonium

Syrup of orange, 5 oz.

A teaspoonful morning and evening.

Sensation of heat may be treated by hydrotherapy, cold douches, or, according to the method of Gortschalk, a warm bath each evening of twenty minutes' duration.

For acne of the face, so frequently observed, pills of ichthyol, as advised by Unna (5 grains twice daily), and lotions of the same agent:—

Ichthyol, 1 dr. Spirit, 2 oz.

Sulphuric ether, 2 oz.
Ess. of thyme, 15 drops.
A teaspoonful in a little water as a lotion.

At night the following ointment might be applied:-

Sulphur, dr.
Talc powder, 1 dr. Oxide of zinc, 1 dr. Ess. of bergamotte, 5 drops. Vaseline Lanoline 4 drops,

If hæmorrhoids be present, cold enemas, belladonna, or rhatania ointment and suppositories of hama-

Ext. of hamamelis vir., 2 gr. Cacao butter, 1 dr.

Vicarious hæmorrhage by the mouth, nose or lung is best treated by rest in bed and ergotin. Hydrastis canadensis is an excellent remedy in such cases: fluid extract, 50 to 80 drops a day; tincture, 20 to 30 drops; hydrochlorate of hydrastin, 2 to 4 grains daily.

Frequently urinary troubles are observed, manifested

by frequenty urinary troubles are observed, manifested by frequent desire to micturate. The symptoms are due, not to cystitis, but to neuralgia of the bladder (cystalgia), and are best treated by warm baths and the introduction of an ovule of solidified glycerine into the vagina; by its detergent action on the uterus great relief is obtained. The internal treatment consists in giving 10 grains of bromide of potassium four times a day, and five days before and five days after the menses 10 drops of tincture of hydrastis cana-densis three times a day. At the same time a bottle of Contrexéville water will be drunk each day before

Metrorrhagia of the critical period is frequently very troublesome, both from its duration and repetition. Injections of very hot water three times a day, and quinine by the mouth (5 grains twice a day) are generally sufficient. To prevent a return, hydrastis canadensis (80 drops daily), and if the patient complains of much pain:

Tincture of Indian hemp, 1 dr. Tincture of hydrastis Tincture of piscidia Tincture of viburnum

Twenty drops in water three times a day. Gelatin seems to give good results. A warm solution of 10 per cent. is injected subcutaneously or employed in plugging. Ovarian extract is also useful, and is of current practice (2 gr. three times a day).

CEREBRO-SPINAL MENINGITIS.

The diagnosis of verebro-spinal meningitis is not always easy, and in some cases almost impossible. Where in adults, or in children old enough to understand the questions put to them the essential features and the usual symptoms of the affection pass easily before one's eyes, and where the malady exists in a sort of epidemic form in a locality where already other cases have been observed, the diagnosis is relatively easy, independent of bacteriological examination. But such is far from being always the case. The disease may be of a sporadic nature, while it frequently attacks very young children, incapable of assisting the physician. Again, it frequently develops, suddenly carrying off the victims in a few days or a few hours, without giving time for a well-established diagnosis and consequent treatment. Prof. Heubner, of Berlin, who is regarded as an authority on the subject, declared that it was impossible to distinguish hyperacute cerebro-spinal meningitis from other forms of meningitis. Grawitz says that the differential diagnosis between tuberculous and sporadic cerebro-spinal meningitis is extremely difficult to establish at the beginning, the clinical forms being about the same.

For Bejinski, on the contrary, a doctor with some experience ought to be able to pronounce on the character of the meningitis. In the cerebro-spinal form, either the child falls suddenly into a comatose state and succumbs after three or four days, or perhaps hours, or the disease may be prolonged several days, the patient maintaining consciousness. In cases of tuberculous meningitis, on the contrary, somnolence persists, progresses gradually with the duration of the malady with, perhaps, periods of lucidity, but they are always short and transitory. In this last affection the fever is generally low, between 100° and 102°, rarely over, while in cerebro-spinal meningitis the temperature is high at the outset, only lowering towards

Never is the stiffness in the neck in tuberculous meningitis as pronounced and persistent as in the cerebral form, where it persists to the end.

In cerebro-spinal meningitis the liquid furnished by the lumbar puncture is remarkable for its abundance; it comes out in a jet, is cloudy and presents a purulent deposit. In tuberculous meningitis the liquid is limpid with a very slight deposit.

Be that as it may, the three capital symptoms of cerebro-spinal meningitis are: Stiffness of the neck, vomiting and headache. One or two of these first symptoms, however, may be wanting, while the third may pass unnoticed, as in the case of very young children. A sign of great value, however, in these latter is the tension of the anterior fontanelle from the increased pressure within.

Examination of the rachidian liquid is the only means of removing doubt as to the nature of the malady. The presence of meningococci and lymphocytes in the liquid is sufficient evidence in most cases.

But where the bacteriological examination is not within reach of the medical attendant, diagnosis is frequently possible without the aid of the laboratory if the following elements furnished by the particular case

are taken into consideration:

The age of the patient; it is said that no other form of meningitis is found in infants.

The bulging forward of the anterior fontanelle in children in whom the cranium is not completely

The fact that the patient maintains consciousness almost intact up to an advanced period of the disease.

The remittent and irregular character of the febrile condition.

The progressive character of the wasting up to the point of emaciation.

The ophthalmic phenomena usually accompanying cerebro-spinal meningitis.

AUSTRIA.

PREVENTING INJURY BY RÖNTGEN RAYS. GOTTWALD gave the Gesellschaft der Aerzte an account of his experiments with the Röntgen rays. He

affirmed that the rays acted on the tissue inversely to its intensity and metabolism. On the tissues of dogs he found when they were compressed and their nutrition diminished the action of the rays was very slight. If this experiment be tried on the cutaneous surface under pressure with either the Röntgen rays or radium it will be found hyperæmic, while the control experiment carried out in the same way without pressure will be found inflamed and the vessels hypertrophied. Again, if the rays be applied to the hairy scalp in the usual way the hair will soon fall out, but if pressure be applied during the exhibition of the rays the hair does not fall out. Hence to protect the tissues under these rays it is necessary to use compression.

TUMOUR ON THE ACOUSTIC NERVE.

Schwarz next presented a man who seven years ago commenced to take giddy turns, followed in a short time by deafness, difficulty to swallow and paralysis in the right side of the palate and vocal cords; the mucous membrane of the trachea was hyperæsthesic, and both parally in the area was appreciated.

and both papillæ in the eyes were congested.

Within the last five weeks these symptoms have changed to a more aggravated form of staggering, right facial paresis and absolute deafness. There is, also, right nystagmus, papillitis, anæsthesia of cornea, a lowered sensation of taste and loss of abdominal reflex, while the tendon reflex was increased on the left side.

He diagnosed the case as one of tumour on the acoustic nerve, compressing the facialis, corpus restiforme, the spinal trigeminus root, and the pyramidal path.

He then discussed the best method of operating in this complicated position.

TUMOUR AT THE BASE OF THE BRAIN. Algyogyi showed a female patient, æt. 37, who for the last ten years has suffered from severe frontal head ache and for the last two years from partial loss of vision. The left pupil did not react to light, the cornea was anæsthetic, and both optic nerves were atrophied. The Röntgen rays revealed a saccular, perforated floating tumour at the base of the brain near the sella turcica. He considered it an osseous tumour in some way connected with the destruction of the sella turcica.

PATHOGENESIS OF ARTERIO-SCLEROSIS.

Biedl and Braun have been carrying out a few laboratory experiments on animals with the hope of demonstrating the proximate or immediate cause of arterial sclerosis. On expounding their views to the Gesellschaft der Aerzte they considered the real cause to be mechanical, and to support this recounted their experiments on dogs where the abdominal aorta was compressed, which produced sclerosis in the thoracic portion of the aorta. This compression was performed on perfectly healthy dogs, leaving no doubt concerning the results. These compressions were made on the aorta immediately above the renal arteries, and only for two minutes daily by pressing the artery against the spinal column. In other cases their experiments were with dry food-stuffs, which certainly produce changes in the structure of the aortic vessels, but not the sclerosis. It cannot be denied that dry food, such as meals, biscuits, etc., is also an active factor in the production of sclerosis, particularly in the small arteries, but the large vessels are not exempted. A peculiar experience was given that absolute hunger, deprivation of food and water was also fruitful in producing sclerosis or changes resembling this pathological condition.

RESPIRATORY GYMNASTICS.

Hofbauer next presented three cases of pulmonary emphysema which he had successfully treated by Freund's method of respiratory gymnastics, which he has practised for several years now. His object was has practised for several years now. His object was to obtain mobility of the costal parietes, and to increase this movement he divided the costal cartilages. All the patients met with the same happy result. Before treatment all were unable to walk or lie down in bed, and were quite cyanotic. Now they are able to walk upstairs with ease and lie down in bed, without any discomfort. The general condition is improved, cyanosis gone, and the heart relieved.

The Royhean method seems to be quite ineffectual in

The Boyhean method seems to be quite ineffectual in restoring the circulation. Dietetic treatment when

exercising the respiratory muscles must not be neglected. The expiratory exercise is important after dividing the cartilages, as it permits of complete contraction of the abdominal muscles and thus greater elevation of the diaphragm.

#### HUNGARY.

Budapest, June 26th 1909.

AT the recent meeting of the Interhospital Association, Dr. Fóth read a paper on

THE ELECTRIC TREATMENT OF UTERINE MYOMATA. He said that in spite of the shortcomings of this method, it has been further studied by many physicians, amongst them by himself. He has even perfected a method which apparently gives satisfactory results. His plan is to produce firm uterine contractions by strong faradisation, with the idea of causing the blood vessels to contract, and thus check the hæmorrhage, while at the same time the nutrition of the thage, while at the same time the nutrition of the tumour is interfered with, and it diminishes in size by a process of absorption. He passes one electrode through the cervix into the uterus, while the other is applied to the abdomen. If possible, the treatment is continued daily from twenty to thirty minutes, and the current is used as strong as the patient can stand Both the strength of the current and the frequency of application must be carefully regulated at the begin-ning of treatment in order not to overtax the patient. The author has never observed any bad effects from the treatment, and has found that the metrorrhagia is entirely controlled and the tumours are greatly reduced in size.

#### INTESTINAL TUBERCULOSIS IN CHILDREN.

In the Orvosok Lapja a type of tuberculosis occurring among the children of coal miners in Hungary is described by Dr. Richter. It affects principally the intestinal lymph glands, and though rarely fatal, may constitute a grave illness. The children fatal, may constitute a grave illness. The children become emaciated, pale, suffer from abdominal pain and tenderness around the umbilicus, headache, insomnia, and slight rise of temperature in the evening. The cervical and sub-maxillary glands are frequently swollen. The disease may progress very rapidly for a time, and then take on a chronic type, which is more time, and then take on a chronic type, which is more apt to be prolonged in the older children. After the subjective symptoms disappear, anæmia, and general weakness persist for a considerable period. The author ascribes the disease to the fact that the local milk supply is of very poor quality and the hygienic conditions are also bad. In view of the fact that Behring states that tuberculosis infection in childhood protects against reinfection later in life, it is interestprotects against reinfection later in life, it is interesting to note that tuberculosis is very rare among the adult inhabitants of the district.

#### DIAGNOSTIC VALUE OF BLOOD EXAMINATION IN SURGERY.

Juffier is reported in the Orvosi Revue as follows:-"Cryptoscopy of the blood is now a method of value in the diagnosis of renal disease. Whenever the increase of molecular concentration shows a persistent insufficiency of the kidneys, nephrectomy ought not to be performed. Unfortunately this method does not give constant results in renal disease; the increase of molecular concentration does not always indicate a bilateral lesion, and even in insufficiency of uræmia the point of molecular concentration may be normal or sub-normal. The hæmoglobin index is valuable. Mikulicz does not operate if it is below 38 per cent. except by means of local anæsthesia. Bloodgood and Cabot do not believe in general anæsthesia if the hæmoglobin is below 70 per cent. The study of the red corpuscles is of less importance to surgery. The iodophil reaction of the leucocytes in suppuration is interesting. Locke, in 800 cases, claimed great value to the test in demonstrating the existence of a focus of suppuration. It has been obtained, however, in gonorrhœal rheumatism.

The presence of leucocytosis is valuable in pointing to hidden purulent inflammation, especially in appendicitis, and a disproportion between the temperature and the leucocytosis is even more important. In rupture of the viscera following a contusion of the abdomen, Cazin has demonstrated a rapid increase

of leucocytes. In intestinal perforation in typhoid fever the hypoleucocytosis suddenly changes to hyperleucocytosis. In carcinoma a gradual diminution of the red corpuscles, an equal decrease of hæmoglobin, and a polynuclear leucocytosis is suggestive of malignancy. In gynæcology it may or may not assist the diagnosis.

#### SCOTLAND.

CHAIR OF SURGERY, UNIVERSITY OF EDINBURGH.-The Curators have invited applications for this Chair, and among the names mentioned in connection with the vacancy are those of Mr. Alexis Thomson, Mr. David Wallace, Mr. W. B. Hodsden, Mr. C. W. Mr. David Wallace, Mr. W. B. Hodsden, Mr. C. W. Cathcart, and Mr. Alx. Miles, all of Edinburgh. Applications, with relatus testimonials, must be lodged with Mr. N. H. Johnston, Secretary to the Curators, 4 Albyn Place, Edinburgh, on or before July 15th. Edinburgh

EDINBURGH INFIRMARY RESIDENTS' CLUB.—On account of the death of Professor Cunningham the

account of the death of Professor Cunningham the Annual Dinner of this club, which was to have taken place this month, has been indefinitely postponed.

MEDICAL INSPECTION OF SCHOOL CHILDREN.—The Edinburgh School Board has agreed to appoint two assistants—one male and one female—to their medical officer, at salaries of £250 and £200 respectively, and two nurses at salaries of £60, to carry on the work of inspection. In Dr. Hally Meikle's report for 1007-8 the following recommendations are report for 1907-8 the following recommendations are made:—(1) More stringent dealing with dirty and verminous children. (2) Following up cases and home visits by nurses to see that orders are obeyed. (3) Schools for special skin diseases, such as favus and ringworm. (4) Relaxation of quarantine regula-tions for minor infectious diseases. (5) Infectious diseases history of pupils to be recorded on their entrance forms. There certainly seems much reason to relax the quarantine regulations, not only in the Board schools, but also in the public schools, in some respects. Edinburgh has this winter been visited by an unusually widely-spread epidemic of mumps, and the result has been that from the need for adhering to the ordinary quarantine regulations the education of the rising generation has been sadly hindered. Classes have been down to a half of the normal number -the average absence has been something like 35 per cent., and it has been no uncommon thing to have had whole families kept from school for several months at a time by reason of successive cases of mumps among them. The question of dealing with infectious diseases in day schools is a difficult one, but it does seem as though, in the case of a disease like mumps, with long incubation and quarantine-periods, and a long period of infectiveness, some-middle path might be found whereby, without unduly exposing the healthy, the extreme rigour of quaranting and withdrawal from school for long periods could be mitigated.

#### LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

SELF-MEDICATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—The evils of self-medication are now seen on Six,—The evils of self-medication are now seen on every hand, and encouragement given by all daily papers, from the *Times* downwards, advertising remedies for all "the ills that flesh is heir to" (thus inincreasing enormously their gains), while the medical practitioner is placed on the same level as the retail chemist. His knowledge, for which he has had to pay well, both by money and risk, goes for nothing in the public estimation, and he is expected to keep the concertable appearance and pay all rates and up a respectable appearance and pay all rates and taxes, and contribute to charity (so-called).

One curse of the nation is self-medication, We find this is literally true, While some in high station prefer operation, And have to pay well for it, too

The chemist advises, sells pills of all sizes,
And capsules and bottles galore,
When folks "can't afford that," then they change coat and hat. And apply at some hospital door.

Free advice they obtain, and they'll try it again, For seldom inquiry is made, And they chuckle and grin at the physic "thrown in," For which they with ease could have paid.

The domestic well-dressed, who struts out in her best, And squanders her wage on a hat, When wanting advice will think over it twice Before she'll pay money for that.

The payment denied to poor doctors outside Finds its way to the public-house till, Or a game at football, or a low music-hall, Legatees—think of this in your will.

I am, Sir, yours truly,

THE EMOLUMENTS OF CHRISTIAN SCIENCE, To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,-May I be permitted to ask Mr. Dixon a purely

business question, apparently involving neither theology, metaphysics, or philosophy?

If Mr. Dixon and his cult claim, as they appear to do, for the work, "Science and Health, with Key to the Scripture," such unprecedented merit, as they never cease to exhort one to consult this book, why do they restrict its circulation by means of a prohibitive price as concerns the great majority of the

general public?

Further, Mr. Dixon will note that the late Dean Farrar's "Life of Christ" and "Renan's Life of Jesus," works of unquestionable great literary merit (both of which I happen to possess) are procurable for the nominal sum of 6d., the "Key to the Scriptures" costing, I believe, twenty times the amount. The veritable Scriptures themselves, at least as regards the "Synoptic Gospels," as they are called, I think, can be had for the nominal price of id. or 2d. If Christian Science is not a moneymaking concern, why do the cult confine their propaganda and literature to the wealthy?

I am, Sir, yours truly, CLEMENT H. SERS.

Brighton, June 24th, 1909.

CHRISTIAN SCIENCE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—The characteristic letter from Mr. Dixon in your current issue needs no more comment than what you append to it. No doubt Mr. Dixon believes all he says, but his belief can be based only on mingled delusion and ignorance. The real character of Christian Science has been fully exposed more than once in your pages, and in that exposure I have several times taken part. To examine it again for a scientific audience would seem very much like breaking a fly for a second time on a wheel; the mere statement of its claims shows it to be simply a farrago of blasphemous nonsense. However, a first-rate writer—the distinguished author of "Confessio writer—the distinguished author of "Confessio Medici"—has taken the trouble seriously to examine in detail the whole question; and to those of your readers who have not seen the book, and wish fully to inform themselves on the subject, I would commend the volume to which I refer. It is entitled "The Faith and Works of Christian Science," and, like all its author's writings, besides being a masterly exposition, it affords a high intellectual treat. With regard to that class of Christian Science practitioner whose methods are the expression of blasphemous imposture, the author sums up their performances in the following passage:—
"They bully dying women, and let babies die in

pain; let cases of paralysis tumble about and hurt themselves; rob the epileptic of their bromide, the syphilitic of their iodide, the angina cases of their amyl nitrite, the heart cases of their digitalis; let appendicitis go on to septic peritonitis, gastric ulcer to perforation of the stomach, nephritis to uræmic convulsions, and strangulated hernia to the miserere mei of gangrene; watch day after day while a man or a woman slowly bleeds to death; compel them who should be kept still to take exercise; and with-hold from all cases of cancer all hope of cure. To these works of the devil they bring their one giftwilful and complete ignorance."

It is amazing that at the opening of the twentieth century, when enlightenment is the boast of our advanced civilisation, there should exist vast masses of the British people as credulous as were the populace in the days of witchcraft. They believe in Christian Science; they spend in these islands annually at least four millions sterling on fraudulent continuously and borne constants. nostrums and bogus apparatus; they flock in crowds to any blatant quack pretender who promises to cure their diseases by methods which could only be explained in every instance by the working of a stupendous miracle.

I am, Sir, yours truly,
A SURREY DOCTOR.

June 25th, 1909.

PREVENTION OF DENTAL CARIES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—It is important that the true cause of rickets should be understood. The writer of the letter signed "M.R.C.S., L.D.S." in this week's MEDICAL PRESS AND CIRCULAR gives to rickets "a first place" among the "constitutional diseases giving rise to the causes of caries," and states that "the main cause of rickets) is improper feeding." The main cause of rickets is not improper feeding. The analysis of 2000 rickets is not improper feeding. The analysis of 3,000 cases of rickets to which reference has been made lately in the British Medical Journal led me to the conclusion that the main cause is some defect in the pulmonary conditions of infants and young children, and that we must look to imperfect blood aeration as the chief cause of rickets.

During the last few years this view, which was published some years ago, has been confirmed by further

observations.

I am, Sir, yours truly, ROBERT LEE.

Pwllheli, June 25th, 1909.

THE "NORMYL" TREATMENT.

To the Editor of The Medical Press and Circular Sir,—I have before me a cutting from your journal of June 23rd commenting upon the Rev. Hugh B. Chapman's recent article on the Normyl Treatment, which appeared in the Daily Mail. You appear to ignore entirely the fact that during the last four years the Normyl Treatment Association has dealt with over 5,000 victims of the drink and drug habits, and that the failures known to the Association number less than 8 per cent. of this total, and we have in our possession 8 per cent. of this total, and we have in our possession hundreds of letters of gratitude and appreciation from patients and friends of patients who have been cured by this treatment. There is a certain eloquence of facts, even in the absence of any medical sanction, and I commend this testimony of the value of the Normyl Treatment to your consideration. I would also add that I know of no human remedy which can possibly prevent a person from drinking who deliberately prefers to do so, but the Normyl Treatment to some extent acts as a substitute for the alcohol, from which we instruct the patient to abstain, and after an almost immediate relief of the craving, so restores the energy and renews the will-power that no patient should thereafter be liable to lapse through sudden temptation. The medicine is gradually increased in strength day by day until a maximum is reached. Afterwards it is as steadily graded down, so that the patient does not come to rely too much upon its tonic effect, and so substitute one habit for another. On this particular aspect of the question a well-known medical man has written as follows:-

"A prescription containing a drug which is very active as (f) a local stiumulant to get rid of alcohol and enable food to be taken, and (2) a general stimulant to produce a feeling of bien three and tide over the dangerous time until the normal vigour and will-power return, must obviously prove phenomenally successful, and such a prescription is presented to the public in the Normyl Treatment."

It is also an interesting fact in the history of our Association that, although when we commenced our work there were fewer than half-a-dozen doctors who would recommend our treatment, to-day, after four years' work, we have over 150 doctors who have prescribed the treatment for their patients, and it is significant that in nearly every case where a medical man has once recommended the Treatment in his practice, he continues to recommend it. I feel sure that this record ought not to be despised, and I do not think that any work carried on in this manner, and with such admirable results behind it, deserves to be hindered.

I am, Sir, yours truly,
WILLIAM PORTEOUS.

June 25th, 1909.
[We publish the above letter because we do not like to be thought to treat unfairly any of those we feel it our duty to criticise. Readers, however, will notice that it meets none of the points we raised, and they will consequently form their own conclusions.—Ed. M. P. AND C.]

### **OBITUARY.**

PROFESSOR D. J. CUNNINGHAM, M.D., F.R.S. THE University of Edinburgh has sustained an almost irreparable loss in the death of Professor Cunningham, which took place on June 23rd. Dr. Cunningham had been in bad health since last autumn, and in December went to Egypt in the hope of regaining strength. As time went on, however, it became all too evident that his symptoms were due to serious organic disease, and since his return to Edinburgh in the spring he has been confined to bed, and gradually losing strength. He suddenly took a turn gradually losing strength. He suddenly took a turn for the worse, and died on Wednesday last. Professor Cunningham—"Dan Cunningham," as he was called by everyone—was the youngest son of the Rev. Principal Cunningham, of St. Andrews. He was born in Crieff, and began the study of medicine at Edinburgh when he was seventeen. In 1874 he graduated M.B., C.M., with first-class honours, and two years later was awarded a gold medal for his thesis on "The Anatomy of the Cetaceæ." From 1876 to 1884 he filled the post of Senior Demonstrator of Anatomy to Sir William Turner, and at the same time Lecturer at the Dick Veterinary College. In March, 1882, he was called to Dublin to fill the Chair of Anatomy at the Royal College of Surgeons, whence, in October, 1883, he was transferred to a similar post at Trinity College, Dublin. On the appointment of Sir William Turner to the Principalship of the University, the Curators took the exceptional course of inviting Cunningham, as the man preeminently fitted to occupy the Chair, to come to Edinburgh as Professor of Anatomy, and since he accepted the post in 1903 he has filled the office with distinction, and has been a great power for good in the councils of the University. Professor Cunningham's eminence in the scientific world is well known. His "Dissector's Guide" and the "Text-book of Anatomy," which he edited, are both recognised as standard authorities on his own subject. Among his best-known memoirs are his report on the Marsupialia, brought home by H.M.S. Challenger, his papers "On the Lumbar Curve in Man and the Apes," "On "On the Lumbar Curve in Man and the Apes," On the Surface Anatomy of the Cerebral Hemispheres," "On Acromegalv and Giantism," "On Right Handedness and Left Handedness," and on the "Anatomy of the Stomach." In all of these his ability as an investigator and his originality as a thinker were well displayed.

Dr. Cunningham acted at one time or another as Examiner in nearly all the Universities and on the Indian Medical Service. He was an Hon. M.D. of

Dublin, D.C.L. Oxon, and LL.D. St. Andrews and Glasgow. He was for eight years Secretary of the Zoological Society of Ireland, and was also Secretary, and Vice-President, of the Royal Society of Dublin, President of the Anatomical Society, of the Anthropological Section of the British Association in 1901, and held office in many other scientific bodies. His ability as a man of affairs, his organising and administrative powers, and his tact and courtesy were among the qualities which led to his services being requisitioned on Boards of Inquiry and Commissions. He served on the Vice-Regal Commission on the Inland Fisheries of Ireland (1900), on the Royal Commission to Inquire into the Care of the Sick and Wounded during the South African War (1901), and on a War Office Committee appointed to report on the Physical Standards Required for Candidates for Commissions and for Recruits. In these various spheres his opinion is for Recruits. In these various spheres his opinion is admitted to have carried great weight, and when Mr. Haldane introduced the Territorial Army Scheme, Cunningham took a leading part in arranging for the medical administration in Scotland. We have not spoken of his personal character, but everyone who ever met or saw Dr. Cunningham must have been extract by the unrightness, simplicity, and kindliness of struck by the uprightness, simplicity, and kindliness of the man. He was one of those happy mortals who attracted liking on the first acquaintance, which, as time went on, developed into affection and esteem. No man was more beloved and respected by his students; during all the years he spent in Edinburgh no one ever had occasion to utter a single disparaging word concerning Dr. Cunningham, and no member of the Senatus was more beloved both inside and outside the University. When any question arose as to medical teaching his was the first counsel sought; he was accessible to all, from the youngest undergraduate upwards, and was always courteous, sympathetic, and wise in advice.

Dr. Cunningham was in his sixty-first year when he died; he is survived by a widow and grown-up family, one of whom is a member of his father's profession.

#### HENRY HUGH BAKER, M.B.

News has been received from the Sleeping Sickness Camp, near Kisii, British East Africa, of the death of Mr. Henry Hugh Baker from malaria, at the age of 31. Mr. Baker was educated at University College, Oxford. He obtained the M.A., M.B., and B.Ch. degrees of the University in the year 1905, and pursued his medical studies at St. Mary's Hospital, London. He was later appointed Government Medical Officer at Nairobi, British East Africa, and had previously acted in the same capacity at Kharga Oasis, West Egypt. Mr. Baker was a member of the British Medical Association and a Fellow of the Society of Tropical Medicine.

## EDMUND MARSHMAN RUSSEL RENDLE, M.R.C.S., L.S.A.

WE regret to announce the death of Dr. Edmund Marshman Russel Rendle, who passed away at his residence, Ivybridge, on June 21rd. For a considerable time the deceased gentleman, who was in his seventy-seventh year, had been in declining health. Born at Plymouth, Dr. Rendle was the son of the late Dr. Edmund Rendle. He inherited his father's love for the medical profession, was accordingly educated at Glenalomand, and passed into King's College Hospital, qualifying at the age of 21. Returning to his native town, he practised for a while in conjunction with his father. Possessing more than average skill, combined with the charm of his personality, Dr. E. M. Russel Rendle was not long in building up an extensive practice, which he continued to conduct for something like 40 years. From 1866 to 1803 he held the position of surgeon to the Royal Eye Infirmary. Among other offices held by him was that of surgeon to the old South Devon Militia, and he was embodied with them during the Crimean War. Dr. Rendle was present at the Whitsands when the awful disaster occurred which bereft him of three near and dear members of his family, and led to the rection of the monument which is a silent witness to the treacherous character of the quicksands below.

HENRY GORST, M.R.C.S., L.R.C.P.
WE regret to record the death of Dr. Henry Gorst, of Huyton. In the districts of Huyton, Prescot, and Knowsley especially the intimation of his death, which took place after a lingering illness was received with unfairned regret. unfeigned regret. A son of the late Dr. Richard Gorst, who was one of the most notable medical practitioners around Liverpool, he entered upon his father's profession, becoming qualified in the year 1877. He worked at the Liverpool Royal Infirmary and St. Thomas's Hospital, London. He has held appointments as House-Surgeon of the Royal Infirmary and the Liverpool Lying-in Hospital, and was also a Visiting Surgeon to the Liverpool North Dispensary, while in the course of a busy life devoted to his profession he made valued contributions to medical journals. Dr. Henry Gorst joined his father in practice at Huyton in 1880. His remarkable devotion to his work—he would scarcely ever tear himself away from an exceedingly busy practice—really undermined his constitution. Three or four years ago he had appendicitis, and latterly suffered from an internal trouble. The death of such an amiable, clever, and conscientious practi-tioner as Dr. Henry Gorst will be deeply mourned by a very wide circle of friends, among whom the poor and needy assuredly must be counted.

### ROBERT WILSON, M.D.ED.

AFTER a short illness we regret to anounce the death of Robert Wilson, of Alloa. Dr. Wilson, who was a native of Limekilns, studied medicine at Edinburgh University, and graduated M.D. in 1858. After practical of the control of the tising for a year in Alva, he came to Alloa in 1859, tising for a year in Alva, he came to Alloa in 1859, and only a few months ago celebrated his jubilee as a local medical practitioner. In 1877 Dr. Wilson was appointed by the old Parochial Board as Medical Officer for the burgh, and he held that appointment up till two months ago, when he retired. He also held the appointments of Medical Officer under the Factory Act and Medical Referee under the Workmen's Compensation Act for the county of Clackmannan.

DR. NATHANIEL HOBART. We very much regret to record the death of Dr. N. J. Hobart, of Cork, who was for a great number of years one of the leading medical men of that city. Dr. Hobart was over 90 years of age, took the M.R.C.S. London in 1846, and the M.D. of Glasgow University in 1847. Amongst the many posts which he held were those of Senior Surgeon to the North Infirmary, Cork, and Consulting Surgeon to the Incurable Hospital, and and Consulting Surgeon to the Incurable Hospital, and
the Hospital for Women and Children. He also served
as President of the Cork Branch of the British Medical
Association and of the Irish Medical Association.

Dr. Hobart enjoyed a large consulting practice
which extended all over County Cork, and although he
had ceased practice for many years he will be remem-

bered with affection and esteem by many of his former patients and friends. His son, Dr. N. Henry Hobart, has succeeded to his practice.

## MILITARY & NAVAL MEDICAL NOTES.

NON-COMMISSIONED officers and men of the R.A.M.C. are to be trained in semaphore signalling with the view of field units of that corps being able to communicate with each other when on active service.

THE Army Council has approved arrangements for the training at Military hospitals of the matrons on the rolls of Territorial General Hospitals. Each of the latter is allowed two matrons, all liable to be called up for training for seven years in alternate called up for training for seven years in alternate years. The hospitals appointed for the training are the R.V. Hospital, Netley; Q.A. Military Hospital, Millbank; Cambridge and Connaught Hospitals, Aldershot; Military Hospitals at Devonport, Woolwich, Cosham, and Colchester. It is proposed that the training time shall be from June till October in each year and the Captal Officers Commanding in each year, and the General Officers Commanding-in-Chief have been directed to send to the War Office as

early as possible the names of matrons who can give attendance for training in the present season.

THE Burma Pasteur Institute is to be situated on an over 3,600 feet above the sea. The main building of the Institute and the Bacteriological Laboratory will be combined in a double-storeyed building. The Vaccine, Pathological, and Parasitological Sections will be in a single-storeyed building. The probable cost will be five lakhs and 78,229 rupees.

THE Gazette of India publishes reconstructed regulations regarding the grant of study leave to officers of the Indian Medical Service. These are as follows:—Study leave may be taken at any time, but will not be granted more than twice in the course of an officer's service. This restriction does not, however, apply to an officer who has part of his furlough converted into study leave under rule 8. Officers on furlough, or other leave, who wish to have part of it converted into study leave, should address the Under-Secretary of State, India Office, and should attach a statement showing how they propose to spend the study leave. Similarly, officers on furlough or other leave who desire to have it extended for the purpose of study should address the Under-Secretary of State, but in addition to the statement of the proposed study, they must support their applications with documentary evidence of their having obtained the approval of the authorities concerned in India to their applying for an extension of leave.

On Tuesday (yesterday), Sir Alfred H. Keogh. K.C.B. Director-General Army Medical Service, gave an address on "The Special Reserve of Officers, Royal Army Medical Corps," in the Medical School, Trinity College, Dublin.

### SPECIAL ARTICLES.

#### HOUSE DISINFECTION IN TUBERCULOSIS.

An editorial note in a recent issue of a medical contemporary emphasises the importance of thorough disinfection of a house recently occupied by a tubercular patient before it is occupied by a new tenant. In the note in question reference is made to an experience related by Dr. F. Lansing Stebbins, of Geneva. U.S.A. Some ten years ago, Dr. Stebbins had a patient who died of tuberculosis. After his death a new tenant moved into the house which he had occu-pied, and a few years later his wife was found to be in the early stage of the disease, a fate which, within the last few months, has overtaken the tenant himself.

Cases such as this have, of course, been well-known for a long time to members of the medical profession. To mention a classic instance, Brouardel relates how 23 clerks in the same employ succumbed to the disease within eleven years of its first appearance in their office. That a phthisical patient must to a greater or a lesser extent infect the rooms which he or she occupies is now generally regarded as axiomatic, and the disinfection of such rooms usually follows as a matter of course.

The Scotch Local Government Board, in its circulars on administrative control of phthisis, urges upon local authorities the need for the disinfection not only of the residences and places of occupation of phthisical sufferers, but also of all places of miscellaneous public resort. Desirable as is this latter measure, it has not yet become a common practice. As has been said, however, the disinfection of the apartments of consumptives is generally carried out. though whether this application is of sufficient frequency, and whether the method of disinfection is always the most efficient, is open to some amount of doubt. In medicine, as in other things, tradition dies hard, and there still exists a general belief in the efficiency of the time-honoured method of fumigation Sulphurous fumigation, especially, is commonly regarded as a suitable method of disinfecting a tuberculous room. Apart from the fact that disinfection

by this method gives the maximum of trouble to those who carry it out, and even offers a certain amount of danger to the occupants of the house in which it is employed, it has been clearly demonstrated that, even with the most stringent fulfilment of all the conditions essential to its successful working, sulphurous disinfection, while undoubtedly efficient against certain organisms, possesses no reliable germicidal action upon the tubercle bacillus. This being so, it is unsatisfactory to find this method so frequently advo-cated in tubercle-infected houses by those who should know better. On grounds alike of convenience, economy, and efficiency, the use of an approved liquid germicide is much to be preferred to fumigation in case of tubercular and some other infections. The main objection to disinfection by this method is the uncertainty of action of certain liquid germicides, and, so long as the unrestricted sale is permitted of so-called disinfectants" which possess little or no germicidal efficiency, that danger must always exist. But it must be remembered that with the employment of modern methods it is possible to determine with exactitude the action of any disinfectant on any particular organism, and accordingly, where disinfection is carried out under the direction of a medical man, there should be no difficulty in ensuring the use of a germicide capable of destroying the tubercle bacillus. As an auxiliary in the battle against tuberculosis, it would be difficult to over-estimate the value of efficient disinfection. Where it is not efficient, howefficient disinfection. Where it is not efficient, how-ever, it is liable to do more harm than good, for it not only means waste of labour and of money, but, by inducing a false sense of security, brings the process into disrepute.

## MEDICAL NEWS IN BRIEF.

Libel on a Doctor.

BEFORE the Recorder, at the Central Criminal Court, on June 23rd, Charles Foxlee, aged 43, leather-dresser, who was convicted at this court in March, 1906, of libelling Dr. Waddell, a retired medical practitioner, now residing in Cornwall, and was bound over to come up for judgment if called upon, surrendered to receive sentence, he having, it was alleged, committed a breach of his recognisance by repeating the libels. Mr. Leycester, counsel for the prosecution, said upon his conviction Foxlee withdrew all the charges against Dr. Waddell and apologised, but he had since broken his promise to obstain from repeating the libels by sending, not only to the prosecutor, but also to his legal advisors, documents repeating the charges and threatening to have the matter printed. Defendant, addressing the Court, alleged that he had been greatly wronged. Eventually he promised not to repeat the libels, and upon this the Recorder allowed the defendant to be released on entering into a fresh recognisance and finding sureties for his future good behaviour. behaviour.

The City of Glasgow and Lord Lister.

The new surgical block of the Glasgow Royal Infirmary was opened on the 23rd inst. by the Lord Provost. A medallion portrait of Lord Lister was on that occasion presented to the managers by past and present members of the staff. An inscription on the framework states that Lord Lister was one of the surgeons of the Royal Infirmary from 1861 till 1869, and that he then organised the antiseptic system of treatment. Mr. Rickman Godlee, Professor of Clinical Surgery to the University College Medical School, a nephew of Lord Lister, gave a short address on Lord Lister and his connection with the Glasgow Royal Infirmary. He paid tribute to Lord Lister's independence in research, his intense patience and earnestness, and his vast achievement.

Hospital Deputation to Mr. Lloyd George.

A MEMORIAL signed by the following gentlemen has been presented to Mr. Lloyd George asking that certain taxes may be remitted in the case of hospitals:—J. Wolfe-Barry, K.C.B. (Westminster), H. Cosmo Bonsor (Guy's), E. H. Bousfield (London Orphan Asylum), Savile Crossley, Bart. (King Edward's Hospital Fund), Alfred de Rothschild (Queen Charlotte's Lying-in Hospital), Hertford (Midland Counties Asylum), Sydney Holland (London and Poplar Hospitals), Portland (Royal Agricultural Benevolent Institution), John Dickens Powder Bart (Greet Northern), Steelback Dickson-Poynder, Bart. (Great Northern), Stradbroke (Eastern Counties Asylum), G. Wyatt Truscott (Lord Mayor).

Mayor).

The institutions represented in the memorial in addition to the above are:—King's College Hospital, General Hospital, Bristol; Royal Infirmary, Liverpool; Royal Blind Pension Society, Royal National Hospital for Consumption, Ventnor; Brompton Hospital, Hospital for Sick Children, Royal Free Hospital, Queen's Hospital for Children, Soldiers' and Sailors' Families Association, Foundling Hospital, Royal Naval Benevolent Society, British Home and Hospital for Incurables, St. Mary's Hospital, Cancer Hospital, Northern Counties Hospital for Incurables, Earlswood Asylum, Victoria Hospital for Children, University College Hospital, General Hospital, Birmingham; General Infirmary, Leeds; Charing Cross Hospital, Middlesex Hospital, Royal Infirmary, Manchester; Meath Hospital, St. Luke's Hospital for Lunatics, Great Northern Central Hospital, Royal Society for Prevention of Cruelty to Animals, Royal London Ophthalmic Hospital, Royal Victoria Hospital, Belfast; St. Thomas's Hospital, Surgical Aid Society, Dr. Barnardo's Homes, Seamen's Hospital Society. Society.

#### The Tuberculesis Act (ireland).

The Dublin Gasette of last week contains Orders under the Tuberculosis Prevention (Ireland) Act, 1908, for (1) prescribing the forms and stages of tuberculosis, to which and the circumstances in which Section I. of the Act shall apply, and (2) making regulations for carrying into effect the provisions of Section I. of the Act, in urban and rural districts to which Part I. of the Act extends.

The first Order declares that Section I. of the Act shall apply to the form of tuberculosis, known as tuberculosis of the lung, "at any stage at which the sputum discharged by the person suffering is in the opinion of the medical practitioner attending on such person liable to communicate the disease to other persons," provided that the section shall only apply in the following circumstances, that is to say, where the person suffering-

(1) Habitually sleeps or works in the same room as any other person or persons not so suffering; or (2) Is employed or engaged in handling, preparing or distributing milk, meat, or any other article of human food intended for sale to the public.

The second order prescribes the rules to be followed by medical practitioners and sanitary authorities in the issuing, registration, and cancelling of the certificates. Both orders come into force on the 1st prox.

Society of Apothecaries of London.

The following candidates, having passed the necessary examinations, have been granted the L.S.A. Diploma of the Society, entitling them to practise Medicine, Surgery, and Midwifery:—E. M. Adam, E. W. Archer, J. Bramley-Moore, J. H. Clarke, L. Ettinger, J. A. Koch, P. N. Panton, and H. O. West.

Conjoint Examinations in Ireland.

THE following candidates have passed the Pre-THE following candidates have passed the Preliminary Examination, June, 1909, as undernoted:—
W. J. A. Laird (with Honours), R. A. Austin, A. J.
W. L. Birchall, I. C. J. Blake, J. Campbell, W. P.
Coney, C. P. F. J. Coyne, G. Dunne, I. J. Eppel, W.
A. N. Fox, F. P. Freeman, T. J. Glynn, M. P. Hatch,
G. Healy, P. E. Kelly, A. Merrin, W. G. D. McCall,
J. B. Minford, N. Mulliner, and J. M. Plunkett.

THERE were 75 cases of cholera reported in St. Petersburg on the 22nd inst., and 76 on the 23rd. The total number of patients in hospital is upwards of 368.

## **NOTICES TO** CORRESPONDENTS. &c.

CORRESPONDENTS requiring a reply in this column are par-ticularly requested to make use of a Distinctive Signature or Initial, and to avoid the practice of signing themselves "Ecader," "Subscriber," "Old Subscriber," etc. Much con-fusion will be spared by attention to this rule.

SUBSCRIPTIONS. SUBSCRIPTIONS.

SYBSCRIPTIONS may commence at any date, but the two valumes each year begin on January let and July let respectively. Terms per annum, 21s.; post free at home or abroad. Fereign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs 15.12. Messrs. Dawson and Sons are our special agents for Canada.

#### ADVERTISEMENTS.

all announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Gd. per line beyond.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

Mrs. H. C. N.—The movement for the "own air school".

should be addressed to the Publisher.

Mrs. H. C. N.—The movement for the "open air school" originated in Germany. There is now a strong and active Association in London, and we shall be pleased to forward to the Secretary any communication you may wish to send.

FALKERIX.—The Liverpool birth-rate has fallen from 37.1 in 1884 to 31.7 in 1908. At the same time, the infantile mortality rate for the latter year is the lowest on record in the history of the city. We hope to deal with the matter at an early date.

the city. We hope to deal with the matter at an early date.

FUEL TO FIRE.

OUR attention has been draw: to a letter in the Jewish Chronicle of June 25th, from a correspondent who signs himself "LAC." The writer is evidently gifted with an acute and a logical mind, for he asks why the Jewish Board of Guardians supply tuberculous patients with milk for which there is no guarantee that it is not infected with tubercle bacilli. Judging from the investigations of Professor Klein, 12.5 per cent, of 32 samples taken at railway stations produced tuberculosis when injected into guinea-pigs. We trust "LAC" will induce the Guardians either to pasteurise their eleemosynary milk, or to insist upon guarantees of purity. But "LAC" has, after all, simply set forth the facts of a grim tragedy that is being played daily at the expense of all classes of society. Let us hope the Hebraic directness of purpose will lighten that particular area of so absurd a practice as feeding tubercular patients with tuberculous milk.

VIATOR.—Violet leaves have been lauded in the properties of the second of the second contractions and the second contractions are a second contractions as feeding tubercular patients with

tuberculous milk.

Viator.—Violet leaves have been lauded in the treatment of cancer, and their therapeutic claims have been weighed in the scientific balance and found wanting. There are many other plans of treatment, but none has yet seriously threatened the efficacy of the knife when used at an early stage.

Mr. J. S. Sargerr.—You are not quite correct in your figures regarding the two cities. The latest figures given in the Registrar-General's official report are:—Liverpool, 760,357; Clasgow, 872,021; so that the claim of the latter as the second largest city in the United Kingdom is correct when based on the number of its population.

## Meetings of the Societies, Lectures, &c.

WEDNESDAY, JUNE 307H

ROTAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, W.O.).—5 p.m.: Dr. G. E. Smith: The Evolution of the Brain. (Arris and Gale Lecture.)

TEXT-BOOK

OF

#### DISBASES 0 F THE EAR.

By Hofrat Professor Dr. A. POLITZER, of Vienna.

Translated at the personal request of the author, and edited by M. J. BALLIN, Ph.B., M.D., Assistant Surgeon, New York Aural Institute, and C. L. HELLER, M.D.

London: Bailliere, Tindall & Cox, 8 Henricia St., Covent Garden.

By W. ARBUTHNOT LANE, M.S.

### Cleft Palate and Hare Lip.

New Edition, in large clear type, demy 4to, 5s.

"Mr. Lane makes out a clear case for early and almost immediate operation. To sum up: Mr. Lane has absolutely proved his contention, and rendered it quite clear that early operation is the right course on every ground, developmental and otherwise; and, further, that delay in performing staphylorrhaphy until the third or sixth year is fraught with most harmful results, and should not be permitted."—British Medical Journal, Jan. 27th, 1906.

### Operative Treatment of Fractures.

New Edition, uniform with above, 7s. 6d.

## The Operative Treatment of Chronic Constipation.

New Edition, uniform with above, 2s. 6d.

THE MEDICAL PUBLISHING Co., LTD., 221 Bartholomew Close, E.C.

Third Edition.

ADAPTED TO THE NEW BRITISH PHARMACOPCEIA, 1885. Medium 8vo, price 21s., or in 2 Vols., 22s. 6d.

## A Text Book of Pharmacology. Therapeutics, and Materia Medica.

By Sir T. LAUDER BRUNTON, M.D., D.Sc., F.R.S.,
Fellow of the Royal College of Physicians; Assistant Physician and
Lecturer on Materia Medica at St. Bartholomew's Hospital; Examiner in Materia Medica in the University of London, in the
Victoria University, and in the Royal College of Physicians, London;
late Examiner in the University of Edinburgh.

ADAPTED TO THE UNITED STATES PHARMACOPEIA BY F. H. WILLIAMS, M.D., BOSTON, MASS.

F. H. WILLIAMS, M.D., BOSTON, MASS.

"It is simply a mine of wealth both for students and practitioners. It is thoroughly practical and thoroughly reliable... is undoubtedly the best treatise on the subject in the English language."—British Medical Journal.

"A work which marks a distinct epoch, a turning-point in the history of medicine. It is not a mere compilation. but is essentially a new departure, breaking away from well-worn tracts into a new and almost unknown region."—Medical Times and Gazette.

## Disorders of Digestion: Their Consequences and Treatment.

BY THE SAME AUTHOR.

This work contains, in addition to the Lettsomian Lectures, a number of other Papers by the Author on similar subjects. 8vo, 10s. 6d.

"Distinguished by accurate observation and original thinking, these papers have been largely instrumental in moulding current medical opinion in regard to many of the subjects with which they are concerned."—Edinburgh Medical Journal.

"We can cordially recommend the volume as one which combines much practical and technical information and sound common sense."—London Medical Record.

Macmillan & Co., Ltd., London.

## Antiphlogistine

(Inflammation's Antidote.)

## AN IDEAL ADJUVANT

For Abdominal Pain and Visceral Inflammation

A rational method of treating locally all forms of disease in which inflammation and congestion play a part.

The Denver Chemical Manufacturing Co., London.

## ANTISCLEROSIN

IN ARTERIO-SCLEROSIS.

## PROPHYLACTIC PAR EXCELLENCE.

Experimental and Clinical Research has shown that this New Medicament is THE BEST for the Treatment of ARTERIO-SCLEROSIS.

Dose: Two Tablets thrice daily.

In Tubes of 32 Tablets.

Samples and Literature post free from—

REITMEYER & CO., 63 Crutched Friars, E.C.

## A Reliable Agent for all forms of Septic Mouth and Throat.

Used with the greatest success in Tonsillitis, Stomatitis, Thrush, etc.

His Excellency Professor von LEYDEN, Berlin University, writes:—

"I have used Formamint Tablets personally and have also prescribed them very frequently, and have been most satisfied with the results."

Professor Dr. Ed. KLEBS writes:-

"Formamint has done me excellent service in the disinfection of the mouth and throat, in Colds and in Influenza associated with laryngeal catarrh."

Samples and Literature free to the Medical Profession on application to A. WULFING & Co., 12, Chenies Street, London, W.C.

The above illustration shows an Agar Plate, the two halves of which were treated with Normal and Formamint Saliva respectively. Both were then inoculated with a typhoid culture. The right half, containing Normal Saliva, developed a virulent growth of the Colonies, whereas on the left half, containing Formamint Saliva, only scratches of the inoculation Spatula are visible. Such is the protection afforded by Formamint against all infectious diseases which effect their entry through the mouth.

## An Efficient Prophylactic against Infectious Diseases,

such as Scarlet Fever, Diphtheria, Measles, etc.

"THE PRACTITIONER," December, 1907, vide Article on "An Analysis of 832 Cases of Scarlet Fever":—

"I regard these lozenges or tablets as a good prophylactic also against sore throat. I have never had a sore throat myself since I began to use them, although I periodically suffered before, and I always recommend their use to the nurses in the scarlet fever wards."

Beware of inefficient substitutes, which, not being chemical combinations, like Formamint, cannot act in the game manner. Insist on "FORMAMINT WULFIRG."

# Formamint

Because they contain the correct amount (B.P. Formulæ) of active ingredients of the highest quality. The water used is of great purity and the beverages are manufactured under the supervision of Scientific Chemists in modern silver-lined machinery.

CAMWAL, Ltd., LONDON, BIRMINGHAM, MANCHESTER, BRISTOL, HARROGAT Head Office: 112 PEMBROKE STREET, LONDON, N. and MITCHAM.

## HOMMEL'S Hæmatogen

CONTAINS NEITHER ALCOHOL NOR ANTISEPTICS

A combination of 90 parts purified and concentrated Hæmoglobin with 20 parts chemically pure Glycerine and Aromatic Flavouring.

The best of all the existing preparations of Hæmoglobin. More efficacious than Cod-Liver Oil or the ordinary manufactured preparations of Iren. Very strengthening both for Children and Adults. An energetic Blood Former. Increases the Appetite. Aids Digestion.

MOST SUCCESSFUL IN THE ANÆMIA AND GENERAL WEAKNESS CAUSED BY MALARIA, ALSO IN IDIOPATHIC ANÆMIA, RICKETS, SCROFULA, DISEASES OF FEMALES, NEURASTRENIA, WEAK HEART, PREMATURE DEBILITY in men. Useful in convalescence after acute diseases such as PNEUMONIA, INFLUENZA, and FEVERS.

FREE FROM BORIC ACID, SALICYLIC ACID, or other chemical preservatives of any kind, as certified by the independent chemical Analysis made by the Incorporated Institute of Hygiene, Devonshire-treet, London, W.

Contains along with purified Hamoglobin all the saits of fresh blood, and valuable compounds of Phospherus, such as Lecithin Phosphete of Sodium, and Phosphete of Potassium, together with the important albuminous constituents of the blood serum, all in a concentrated, purified, and undecomposed state.

In prescribing, always state "HOMMEL'S" Hæmatogen ac spurious imitations are offered.

ONLY SUPPLIED IN FLUID, NOT IN CAPSULES OR OTHER FORMS.

Infants - - Take from Half to One Teaspoonful twice a day in milk.

. One or Two Dessertspoonfuls daily, either pure or mixed with any convenient liquid.

Adults - - . One Tablespoonful twice a day before the two principal meals.

SAMPLES AND LITERATURE, gratis and carriage paid, on application.

NICOLAY & CO., 36 & 36a, ST. ANDREW'S HILL, LONDON, E.C.

## Xeroform

Powder for wounds; absolutely non-poisonous, non-irritant, sterilisable. Applied to aseptic wounds in a thick layer, Xeroform prevents the dressing adhering to the wound, the

retention of discharge and suppuration along the path of the stitches. In burns, intolerable pain is at once relieved, healing is rapid with very little discharge, and the scar is smooth and delicate. A specific in moist eczema and in chronic ulcers of the leg.

A rapidly curative remedy, relieving pain, in **rheumatic** troubles; to be rubbed into the skin in muscular rheumatism, acute neuralgia, teno-synovitis, rheumatic pleurisy.

Salit is tolerated by the skin undiluted. No secondary actions.

Novargan

Renders possible a powerfully bactericidal treatment of gonorrhea, for being non-irritant, it may be used in comparatively high concentration.

disinfects the urinary passages by the liberation of Formaldehyde in acid or alkaline urine; it rapidly imparts an acid reaction to the urine, and it has no irritant action on the

digestive canal or the kidneys.

Samples and Literature gratis of

# "LIQUOR CARBONIS DETERGENS"

REGISTERED TRADE MARK)

## (WRIGHT'S)

The necessity for this request is made apparent in the "Chemist and Druggist," which says—

The B.P. preparation (Liq. Picis Carbonis) is, it should be noted,

### MUCH BEHIND THE ORIGINAL

and differs from it in composition, and therefore in efficacy. We call the attention of Dispensers to this point because it seems natural to suppose that when the B.P. imitates an article such as 'Liquor Carbonis Detergens' it is not immoral to substitute the official preparation for the proprietary one. This is, of course, absurd, because the compilers of the British Pharmacoposia have

#### NO MORE RIGHT TO INFRINGE

other people's proprietary rights than the man in the street."

46. YEARS' REPUTATION.

WRIGHT, LAYMAN & UMNEY, Ltd., SOUTHWARK, LONDON.

## The New Dietetic Preparation.

OVALTINE is a dietetic preparation—in granular powder form—of high therapeutic value, made of Malt Extract, Fresh Eggs, Milk, and Converted Cocoa, and containing Active Legithin.

Extremely Nourishing and highly Restorative.

Very Palatable and acceptable to the most delicate stomach.

Simple to prepare.

The best substitute for Tea, Coffee, &c., and the only preparation of this kind containing Organic Phosphorus (Lecithin).

A powerful Digestive Agent and a Nervine Tonic of the highest order.

## OVALTINE

is the remedy par excellence in Convalescence, Neurasthenia, Faulty Digestion, Malnutrition, Brain Fag, Over Study, and Exhaustion. Readily assimilated and particularly adapted for the over-feeding of the Tuberculous. Suitable for infants, youths, adults, and the aged.

OVALTINE is packed in 42 oz., 9 oz. and 18 oz. tins. LITERATURE AND SAMPLE FREE TO MEDICAL MEN.

A. WANDER, Ph.D., Manufacturing Chemist, 1 Leonard St., City Re., LONDON, E.C.

Have you noticed that an injection or instillation of

## ARGYROL

(SILVER VITELLIN)

relieves the pain of local inflammation, while all other silver salts increase the pain? Moreover, scientific studies prove that Argyrol quickly destroys gonococci.

These facts explain why Argyrol is considered, the world over, a superior remedy in the treatment of gonorrhœa (injection of 10 per cent. solution every three hours) and other inflammations of the eye, throat, nose and ear (25 per cent. solution instillation or local application).

Produced by

## A. C. BARNES COMPANY

32 SNOW HILL, LONDON, E.C.

The following statement concerning

## OVOFERRIN

(IRON VITELLIN)

is a copy from the official records of the largest clinic in Germany where the remedy has been in continuous use for more than four years:

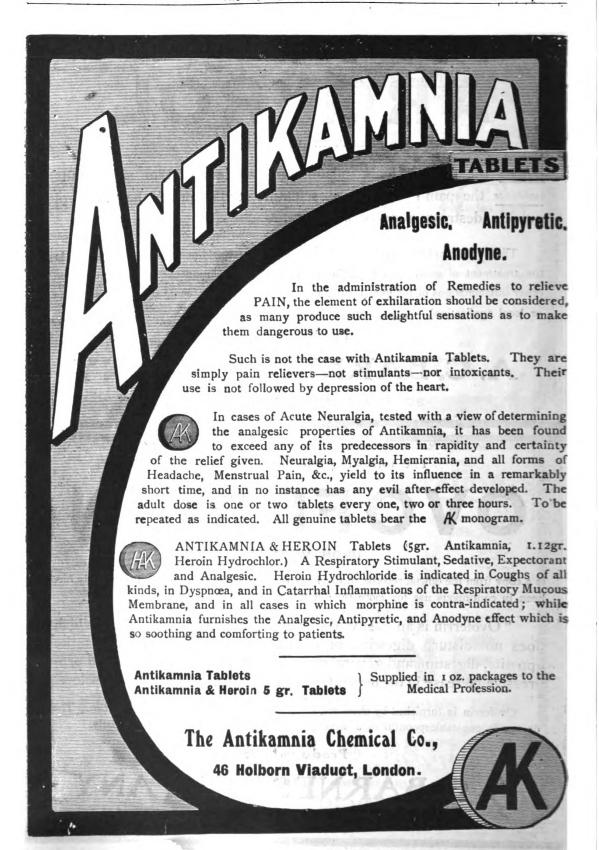

"Ovoferrin is an easily assimilable, well tolerated remedy which does not disturb digestion or cause constipation, but improves the appetite, digestion and general nutrition, and produces steady and progressive increase in the percentage of hæmoglobin and red corpuscles."

Ovoferrin is furnished by chemists, on prescription, in twelve ounce bottles. The dosage is one tablespoonful in a wine-glass of water or milk three times daily.

The

# Allenburys Foods

## Special Advantages:

- 1—The close conformity in composition of the Milk Foods to human milk; both fat and proteids being in similar relative proportions.
- 2—The readiness with which the Foods are assimilated; being as easy of digestion as maternal milk.
- 3—Their adaptability as an adjuvant to breast feeding during the period of weaning; no digestive troubles being likely to occur.
- 4—Their freedom from all harmful bacteria; being made from fresh milk, modified, evaporated at a low temperature, in vacuo, and preserved in hermetically sealed tins.
- 5—The ease and exactness with which the Foods can be prepared; the addition of hot water only being necessary.
- 6—Fresh elements of diet can be easily added to the Foods, and are specifically mentioned on each tin.

A reliable substitute is thus provided for the Mother's Milk, when this is wanting or deficient.

MILK FOOD No. 1.

## ST. PATRICK'S HOSPITAL FOR MENTAL DISEASES.

THE GOVERNORS OF

## ST. PATRICK'S HOSPITAL, DUBLIN.

(FOUNDED BY DEAN SWIFT IN 1745),

Wish to announce that they have acquired a large property, in accordance with their Royal Charter (300 acres), and established a Private Asylum in connection with the Hospitals at Lucan for the reception of patients of both sexes suffering from Mental

Disease.

A NEW VILLA has been erected at Lucan for the accommodation of a limited number of gentlemen, and the entire establishment has been lighted by electricity.

The parent institution in Dublin continues its curative work, has undergone almost entire reconstruction, receives both male and female patients, and its recovery rate is very satisfactory. The Governors are anxious that the Medical Profession should be acquainted with the work of this historic institution, which has been devoted for over a century and a half to the reception and curative treatment of the insane of Ireland.

Urgent cases can be admitted by direct application to the Medical Superintendent.

For further particulars, forms of admission, &c., apply to the REGISTRAR, St. Patrick's Hospital, James Street, Dublin.

#### PRIVATE ASYLUMS,

Co. DUBLIN.

For the Cure and Care of Patients of the Upper Class suffering from Mental and Nervous Diseases, and the Abuse of Drugs. Established 1825.

HAMPSTEAD.

HIGHFIELD. CLASHEVIN; FOR GENTLEMEN. | DRUMOONDRA, FOR LADIES.

Telephone No. 1082.

These Hospitals are built on the Villa System, and there are also Cottages on the demense (154 acres), which is 100 feet above the sealest, and commands an extensive view of the Dublin Mountains and Bay.

Voluntary Patients admitted without Medical Certifica

For further information apply for illustrated prospectus, &c., to the Resident Medical Superintendents, Dr. HERRY MARGUS EUSTAGE, Highfield, Drumoondra, or Dr. WILLIAM RELISON EUSTAGE, Hampstead, Glamevin; or at the office, 41 Grafton Street, Dublim Telephone 196. On Mondays, Wednesdays and Fridays, from 2 to 3 p.m.

## THE ONLY ASEPTIC PEEDER MADE

IS THE ROTUNDA FEEDING BOTTLE

It is simple—only a pure rubber test and bottle—no valve. It is safe—for it can be sterilised. It is cheap—Sci.-

Can be had wholesale from any Druggists' Sundry House, or from

LEONARD & CO., Chemists, Dublin & Belfast. Leonard's Rotunda Tissue, 1/- per lb.

Leonard's Clinical Thermometers, 1/- each.

# Collis Browne's

THE ORIGINAL AND ONLY GENUINE.

From Symes & Co., Chemists, Medical Hall, Simla, January 5th, 1880-

To J. T. DAVENPORT, Esq., London,

DEAR SIR,—Have the goodness to furnish us with your best quotations for Dr. J. Collis Browne's Chlorodyne. We embrace this opportunity of congratulating you upon the widespread reputation this justly esteemed medicine has earned for itself, not only in Hindostan, but all The other brands are now relegated to the native bazaars, and judging from their over the East. sale, we fancy their sojourn there will be but evanescent. We could multiply instances ad infinitum of the extraordinary efficacy of Dr. Collis Browne's Chlorodyne in Diarrhoea and Dysentery, Spasms, Cramps, Neuralgia, the Vomiting of Pregnancy, and as a general sedative, that have occurred under our personal observation during many years. In Choleraic Diarrhœa, and even in the more terrible forms of Cholera itself, we have witnessed its surprisingly controlling power. We have never used any other form of this medicine than Collis Browne's from a firm conviction that it is decidedly the best, and also from a sense of duty we owe to the profession and the public, as we are of opinion that the substitution of any other than Collis Browne's is a deliberate breach of faith on the part of the chemist to prescriber and patient alike. We are, Sir, faithfully yours,

SYMES & CO., His Excellency the Viceroy's Chemists.

WHEN PRESCRIBING CHLORODYNE, REMEMBER TO ADD THE NAME OF "DR. J. COLLIS BROWNE." OTHER-WISE A SUBSTITUTE MAY BE DETRIMENT OF THE PATIENT.

Sole Manufacturers, J. T. DAVENPORT, Ltd., 117 Union St., London, S.E. Formerly 33 Great Russell St., W.C.

## DIET IN WEAKENED DIGESTIVE POWER

BENGER'S FOOD is a cereal preparation free from rough indigestible particles and containing the natural digestive principles, trypsin and amylopsin.

It is expressly devised to be used in conjunction with fresh milk or milk and water in such proportions as may be considered advisable for the particular case.

The composition of the prepared food, ready for consumption, varies with the formula used and the length of pre-digestion ordered. The fat may be increased by the addition of cream, or the use of upper milk, if desired :: ::

Sample, together with Analysis and Report, sent to any member

of the Medical profession on application to
